1. Abstract / Executive Summary

The *Smart Attendance System Using Face Recognition* is an automated and intelligent system designed to replace traditional attendance marking methods in educational institutions and organizations.

The system uses computer vision and machine learning techniques to identify individuals based on facial features and automatically records their attendance in a centralized database.

The proposed system captures live images through a camera, detects faces, performs face recognition and updates attendance records in real time. This approach significantly reduces manual effort, eliminates proxy attendance and improves the accuracy and reliability of attendance records.

The system also provides administrative control, report generation and data analysis facilities for effective attendance management

1. Introduction

The Smart Attendance System is designed to automate attendance using facial recognition technology. The system works through three main processes: **Registration, Mark Attendance, and Admin Panel**.

Registration

The user visits the **Register page** and enters details such as full name, email address, and roll number. The system validates the entered information to ensure there are no duplicate email addresses or roll numbers and that the name format is correct. After validation, the user is redirected to a **Capture Photo page**, where the browser camera is activated to capture the user's facial image.

The system detects the face in the captured image and generates a **face encoding**. This encoding is stored in the **MySQL database** along with the user's information. The system also checks for duplicate faces to prevent the same person from registering multiple times under different identities.

Mark Attendance

To mark attendance, the user visits the **Mark Attendance page** and allows camera access. The system captures the user's face through the webcam. The captured face image is compared with all stored face encodings in the database.

If a matching face is found and the user has not already marked attendance for that day, the system records the attendance in the database along with the **current date and time**. A confirmation message is displayed to the user. If the face is not recognized or attendance has already been recorded for the day, the system displays an appropriate message.

Admin Panel

The system includes an **Admin Panel** for administrative management. The administrator logs in using a secure username and password. After successful authentication, the admin can access a dashboard that displays **total registered users** and **today's attendance count**.

The admin can view a list of all registered users, today’s attendance report (including name, roll number, and time of attendance), and monthly attendance reports showing the number of days present and the attendance percentage for each user. The system also provides settings where the admin can **clear attendance by date, clear all attendance records, delete individual users, or remove all users** from the database.

Session-based authentication ensures that only authorized administrators can access these administrative features.

2.3 Need for the System

The need for the Smart Attendance System arises due to several limitations of traditional attendance methods.

First, **time consumption** is a major issue. In large classrooms or organizations, manually calling roll numbers takes valuable time that could otherwise be used for productive activities such as teaching or meetings.

Second, **proxy attendance** is a common problem in manual systems where one person may mark attendance on behalf of another. Face recognition technology eliminates this issue by verifying the identity of each individual using their unique facial features.

Third, **human errors** frequently occur in manual attendance records. Teachers or administrators may accidentally mark incorrect entries, miss students during roll calls, or maintain poorly organized records. Automating attendance reduces such errors.

Fourth, institutions require **accurate and easily accessible reports**. Generating daily and monthly attendance reports manually can be difficult and time-consuming. By storing attendance data in a database, the system can automatically generate reports whenever required.

Finally, the system provides a **contactless solution**. Unlike fingerprint scanners or other biometric devices that require physical contact, this system uses only a webcam and browser, making it more hygienic and easier to deploy.

2.4 Features

The Smart Attendance System provides several important features that improve attendance management:

User Registration with Face Capture
Users can register by entering their name, email address, and roll number. After registration, the system captures the user's facial image through the webcam. The system validates the data format and checks for duplicate email addresses, roll numbers, and facial identities before storing the information in the database.

Attendance Marking via Face Recognition
Users can mark their attendance by capturing their facial image on the attendance page. The system matches the captured face with stored face encodings and records attendance only if a match is found. The system allows only one attendance record per user per day.

Admin Dashboard and Reports
The admin dashboard displays key information such as the total number of registered users and the number of users who marked attendance on the current day. The administrator can also view detailed attendance reports.

Attendance Management
The admin can clear attendance records for a specific date or remove all attendance records when required. The system also allows administrators to delete individual users or remove all users from the system.

Responsive User Interface
The system interface is designed using **Bootstrap and custom CSS**, ensuring that the application works smoothly on both desktop and mobile devices.

Flash Messages for Feedback
The system displays success and error messages to inform users about the result of their actions such as registration, login, and attendance marking.

3. OBJECTIVES OF THE PROJECT

The main objective of the **Smart Attendance System using Face Recognition** is to automate the process of attendance management in educational institutions or organizations. The system uses facial recognition technology to identify individuals and record their attendance in a secure and efficient manner.

This system aims to reduce the limitations of traditional attendance systems such as manual errors, proxy attendance, and time consumption. By integrating computer vision and web technologies, the system provides an accurate and user-friendly method for recording attendance.

3.1 Primary Objectives

1. Automate Attendance Process

The primary objective of the project is to automate the attendance process using facial recognition technology. Instead of manually marking attendance, the system captures the user's face and identifies them automatically.

2. Eliminate Proxy Attendance

The system ensures that attendance can only be marked by the registered individual. Since facial features are unique to every person, it prevents proxy attendance and ensures authenticity.

3. Improve Accuracy of Attendance Records

Manual attendance systems are prone to errors such as incorrect entries or missed records. The automated system ensures accurate data storage and reduces the chances of human error.

4. Provide a Web-Based Attendance System

The system is designed as a web application so that users can access it through a browser without installing additional software. This makes the system easy to use and accessible from multiple devices.

5. Generate Attendance Reports

The system allows administrators to generate daily and monthly attendance reports. These reports help institutions monitor attendance records and analyze attendance trends.

3.2 Secondary Objectives

1. Secure Storage of Data

The system stores user information and attendance records in a MySQL database. This ensures organized data management and easy retrieval of information when needed.

2. User-Friendly Interface

The system is designed with a simple and responsive user interface using Bootstrap so that users can easily interact with the system on both desktop and mobile devices.

3. Easy Administration

The admin panel allows administrators to manage users, view reports, and maintain attendance records efficiently.

4. Scalable System Design

The system is designed in such a way that it can be expanded in the future to include more features such as mobile applications, cloud storage, and integration with institutional management systems.

4. SCOPE OF THE PROJECT

The scope of the **Smart Attendance System** defines the functionalities that are included in the project and the limitations of the system.

The project focuses on developing a **web-based application** that records attendance automatically using facial recognition technology. The system allows users to register their personal information and facial data, which is later used to verify their identity when marking attendance.

The system includes features such as user registration, face capture, attendance marking, admin dashboard, attendance reports, and data management.

In Scope

The following features are included in the project:

- User registration with name, email, roll number, and facial image capture.
- Validation of user input data during registration.
- Detection of faces using a webcam.
- Face recognition to identify registered users.
- Automatic recording of attendance with date and time.
- Prevention of duplicate attendance for the same day.
- Admin login and authentication.
- Dashboard displaying total users and attendance statistics.
- Viewing lists of registered users.
- Viewing daily and monthly attendance reports.
- Clearing attendance records when required.
- Deleting users from the system.
- Responsive user interface for easy accessibility.

Out of Scope

The following features are not included in the current version of the project:

- Mobile application for Android or iOS.
- SMS or email notifications for attendance.
- Integration with existing ERP or college management systems.
- Multi-institution or multi-branch support.
- Hardware biometric devices such as fingerprint scanners.

These features may be implemented in future versions of the system.

5. REQUIREMENT & ANALYSIS

Requirement analysis is an important phase in software development. It involves identifying the hardware and software resources needed to develop and run the system efficiently. In the Smart Attendance System, both hardware and software requirements are defined to ensure smooth functioning of the web application and the face recognition process.

This section describes the minimum hardware specifications, software technologies, and system requirements necessary to implement the Smart Attendance System.

5.1 Hardware Requirement:

The Smart Attendance System requires basic hardware components to run the application and capture facial images for recognition. The following table shows the hardware specifications required for the system.

Component	Specification
Processor	Intel Core i3 / AMD equivalent or above
RAM	4 GB minimum (8 GB recommended)
Storage	500 MB free space for application and database
Camera	Webcam / built-in camera for face capture (720p or higher recommended)
Display	1024 × 768 or higher resolution
Network	LAN or Wi-Fi connection for server access

The processor and memory requirements ensure that the application runs smoothly while performing face detection and database operations. A webcam is necessary for capturing facial images during registration and attendance marking. A stable network connection is required so that users can access the web application hosted on the server.

5.2 Software Requirement:

The software requirements include the operating system, programming languages, libraries, frameworks, and tools used for developing and running the Smart Attendance System.

Component	Technology
Operating System	Windows 10/11, Linux, or macOS
Backend	Python 3.8+, Flask
Database	MySQL 5.7+ or MariaDB
Face Detection	OpenCV, NumPy
Image Processing	PIL / Pillow
Frontend	HTML5, CSS3, JavaScript, Bootstrap 5
Database Connector	mysql-connector-python
Browser	Google Chrome, Mozilla Firefox, Microsoft Edge (with camera support)

Python is used as the main programming language because of its strong support for computer vision libraries. Flask is used as the backend framework to build the web application. OpenCV is used for face detection and image processing, while MySQL is used to store user and attendance data. Bootstrap is used to create a responsive and user-friendly interface.

5.3 Software Requirements Specification (SRS):

The Software Requirements Specification defines the functional and non-functional requirements of the Smart Attendance System.

Functional Requirements

FR1: The system shall allow users to register by entering their name, email address, roll number, and capturing their facial image.

FR2: The system shall validate user input to ensure that the name contains only alphabets, the email format is valid, and the email and roll number are unique.

FR3: The system shall detect the face in the captured image and store the face encoding in the database. If no face is detected or if a duplicate face is found, the system shall reject the registration.

FR4: The system shall allow registered users to mark their attendance by capturing their facial image through the webcam. Only one attendance record per user per day shall be allowed.

FR5: The system shall allow administrators to log in securely using a username and password. After login, the admin session shall remain active until logout.

FR6: The system shall provide an admin dashboard that displays the total number of registered users and the number of users who marked attendance on the current day.

FR7: The system shall allow administrators to view a list of registered users, view daily attendance reports, generate monthly attendance reports, clear attendance records by date or completely, and delete user records.

Non-Functional Requirements

NFR1: The system shall be accessible through a web browser within the same local network or server environment.

NFR2: The system shall perform face recognition and attendance marking within an acceptable response time (typically less than five seconds).

NFR3: The user interface shall be responsive and compatible with both desktop and mobile browsers.

NFR4: The system shall maintain data integrity and ensure secure storage of user information in the database.

NFR5: The system shall provide reliable performance and minimize system downtime.

5.4 Justification of Selection of Technology:

The technologies used in the Smart Attendance System were selected based on their efficiency, reliability, and compatibility with face recognition applications.

Flask

Flask is a lightweight and flexible web framework for Python. It is suitable for small to medium-scale web applications and provides easy integration with OpenCV and MySQL. Flask also simplifies routing, template rendering, and session management.

OpenCV

OpenCV is a widely used open-source computer vision library. It provides efficient algorithms for image processing and face detection. The Haar Cascade classifier used in OpenCV can detect frontal faces quickly and accurately.

MySQL

MySQL is a reliable relational database management system that supports structured data storage, transactions, and foreign key relationships. It is widely used in web applications and provides efficient querying and reporting capabilities.

Bootstrap

Bootstrap is a popular frontend framework that helps developers build responsive and visually consistent user interfaces. It speeds up development by providing ready-to-use components such as forms, navigation bars, and tables.

Python

Python is known for its simplicity, readability, and extensive library support. It is widely used in machine learning, artificial intelligence, and image processing applications, making it an ideal choice for implementing a face recognition-based attendance system.

6. SYSTEM DESIGN

System design is an important stage in software development where the overall architecture of the system is planned. It describes how different components of the system interact with each other to perform required operations.

For the **Smart Attendance System**, the system design includes several diagrams and models that represent the structure and working of the application. These diagrams help developers and stakeholders understand how the system functions and how data flows between different modules.

The system design includes diagrams such as **Entity Relationship Diagram (ERD), Data Flow Diagram (DFD), Use Case Diagram, Class Diagram, Sequence Diagram, Activity Diagram, State Diagram, Collaboration Diagram, Component Diagram, and Package Diagram**.

6.1 ER Diagram (Entity Relationship Diagram):

The **Entity Relationship Diagram (ER Diagram)** represents the structure of the database used in the Smart Attendance System. It shows the relationship between different entities such as users, attendance records, and administrators.

Main Entities

Users Table

This table stores information about registered users.

Attributes:

- User ID (Primary Key)
- Name
- Email
- Roll Number
- Face Encoding
- Registration Date

Attendance Table

This table stores attendance records of users.

Attributes:

- Attendance ID (Primary Key)
- User ID (Foreign Key)
- Date
- Time

Admin Table

This table stores administrator login credentials.

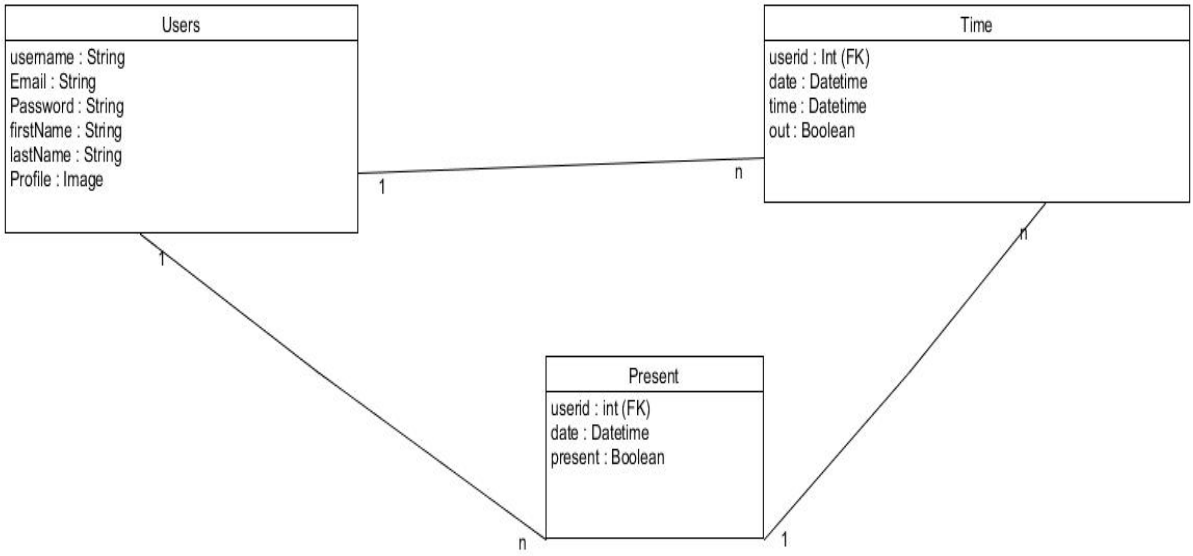
Attributes:

- Admin ID
- Username
- Password

Relationships

- One user can have many attendance records.
- Each attendance record belongs to one user.
- Admin manages users and attendance records.

The ER diagram helps in understanding how data is organized and stored within the database.



6.2 DFD Diagram (Data Flow Diagram):

A **Data Flow Diagram (DFD)** shows how data moves through the system and how different processes interact with data storage and external entities.

DFD Level 0 (Context Diagram)

The Level 0 DFD represents the system as a single process interacting with external entities.

External Entities:

- User
- Admin

Processes:

- Register User
- Mark Attendance
- Manage Attendance

Data Store:

- Database (Users and Attendance records)

The user provides input such as registration details or face capture, and the system processes the data and stores it in the database.

DFD Level 1

The Level 1 DFD breaks down the system into multiple processes.

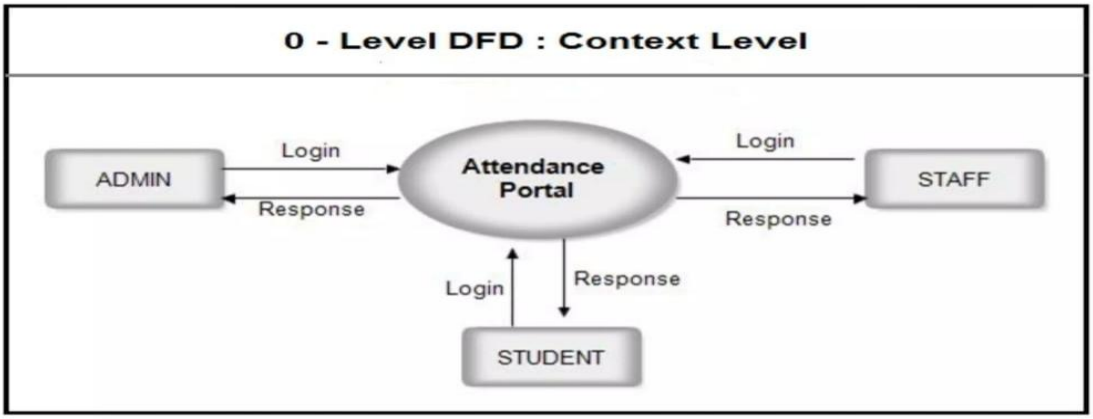
Processes include:

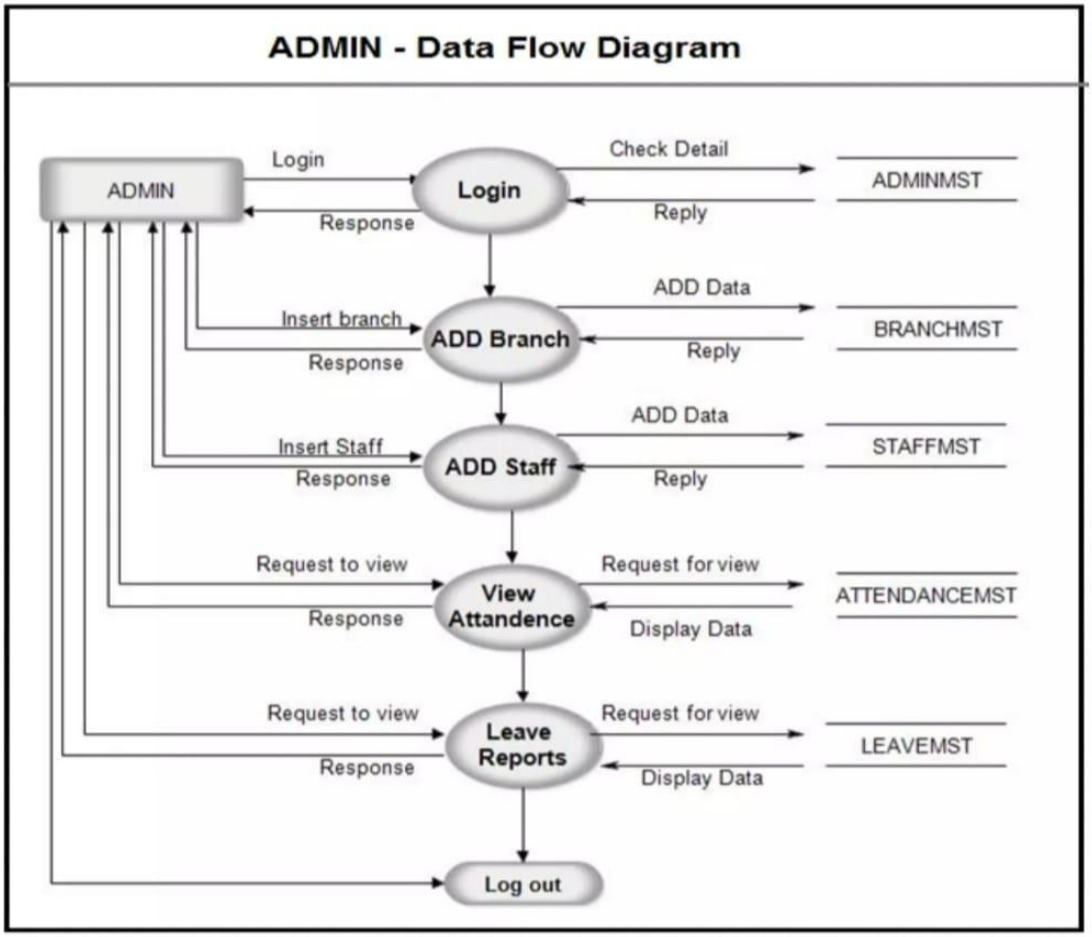
1. User Registration
2. Face Capture and Encoding
3. Attendance Verification
4. Attendance Recording
5. Admin Login and Management

Data stores include:

- User Database
- Attendance Database

This diagram shows how information flows between the user, system processes, and database.





6.3 Data Dictionary:

A **Data Dictionary** describes the structure of data elements used in the database.

User

No	Field name	Data type	Required	Unique	PK / FK	Ref. Table
1	UserId	int	true	true	PK	-
2	Email	string	true	true	-	-
3	Name	string	true	false	-	-
4	Password	string	true	false	-	-
5	CreatedAt	Datetime	true	false	-	-
6	UpdatedAt	Datetime	True	False	-	-

Present

No	Field name	Data type	Required	Unique	PK / FK	Ref. Table
1	PId	int	true	true	PK	-
2	Date	Datetime	True	False	-	-
3	User	User	True	False	FK	Users
4	Present	Boolean	True	False	-	-

Time

No	Field name	Data type	Required	Unique	PK / FK	Ref. Table
1	TId	int	true	true	PK	-
2	Date	Datetime	true	True	-	-
3	User	Users	True	False	FK	Users
4	Time	Datetime	False	False	-	-
5	Out	Boolean	True	False	-	-

6.4 Database Normalization:

Database normalization is the process of organizing database tables to reduce redundancy and improve data integrity.

The Smart Attendance System database follows **Third Normal Form (3NF)**.

First Normal Form (1NF)

- Each table contains atomic values.
- No repeating groups of data.

Example:
Each user record stores only one email and one roll number.

Second Normal Form (2NF)

- All non-key attributes depend on the primary key.
- Attendance records depend on the user ID.

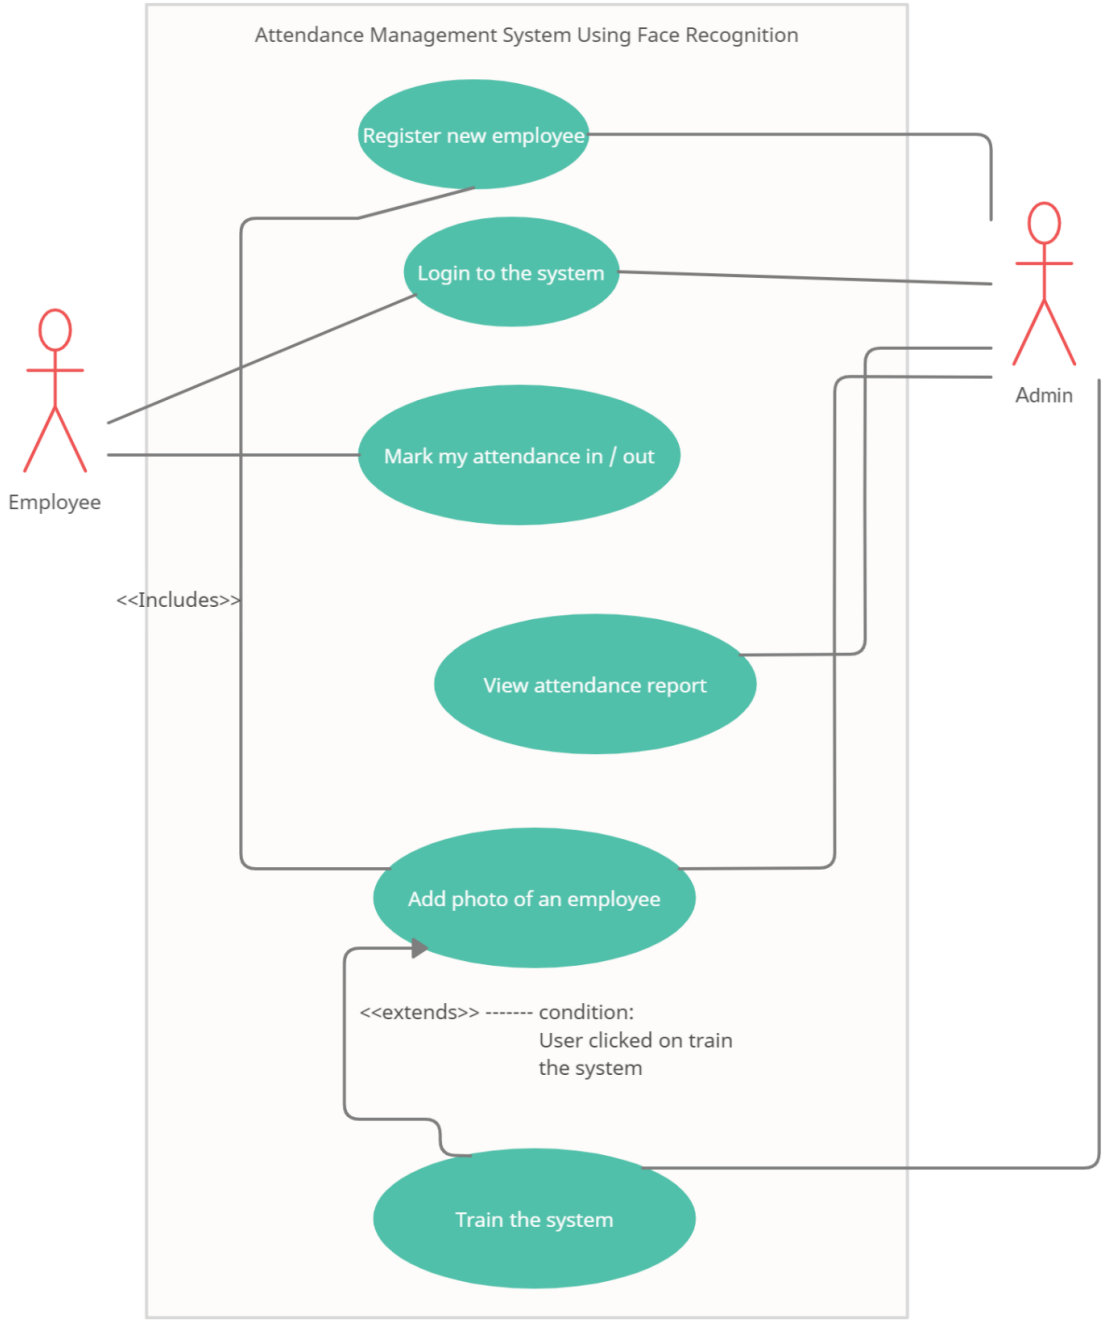
Third Normal Form (3NF)

- No transitive dependency exists.
- User information is stored separately from attendance records.

Normalization ensures efficient storage and easier database management.

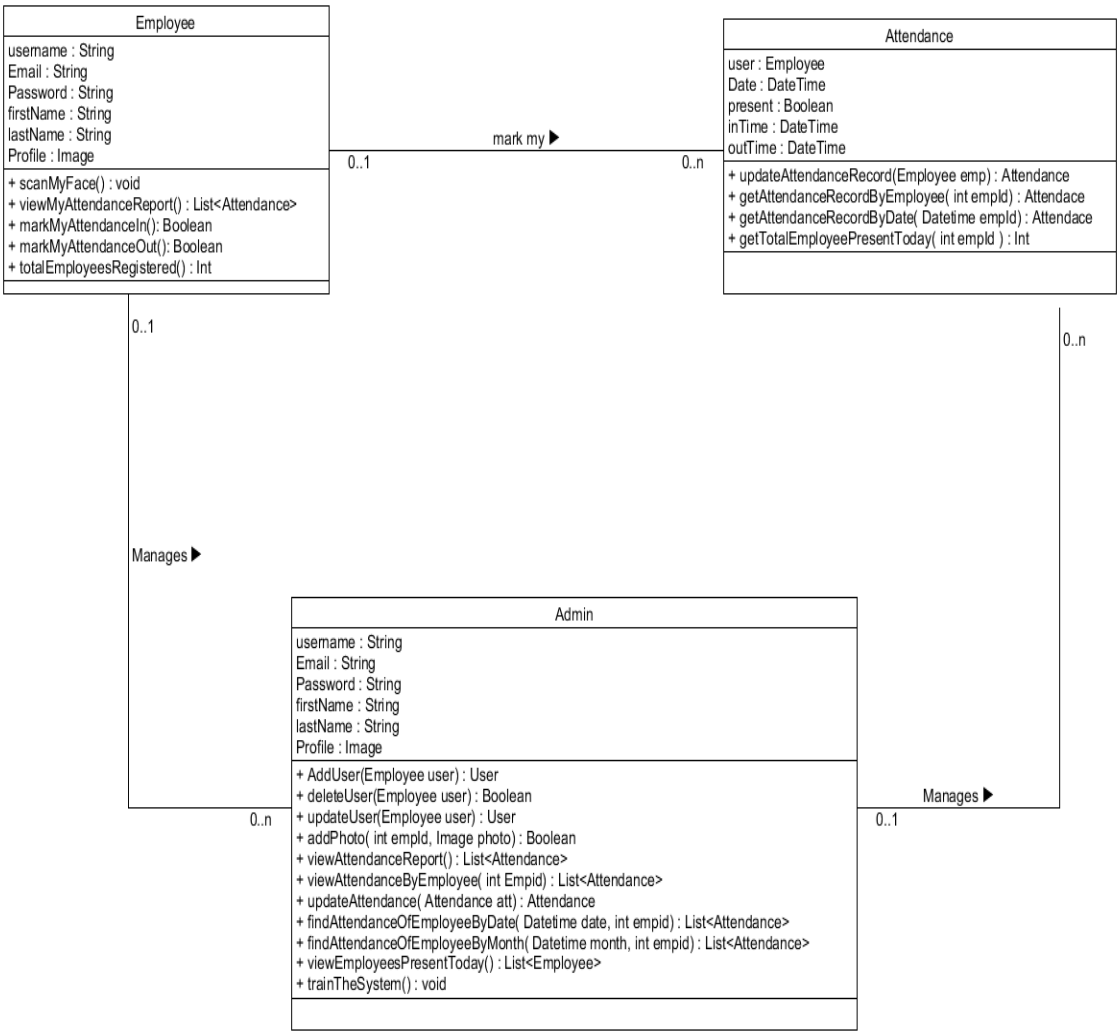
6.5 Use Case Diagram:

The **Use Case Diagram** shows the interaction between system users and the application.



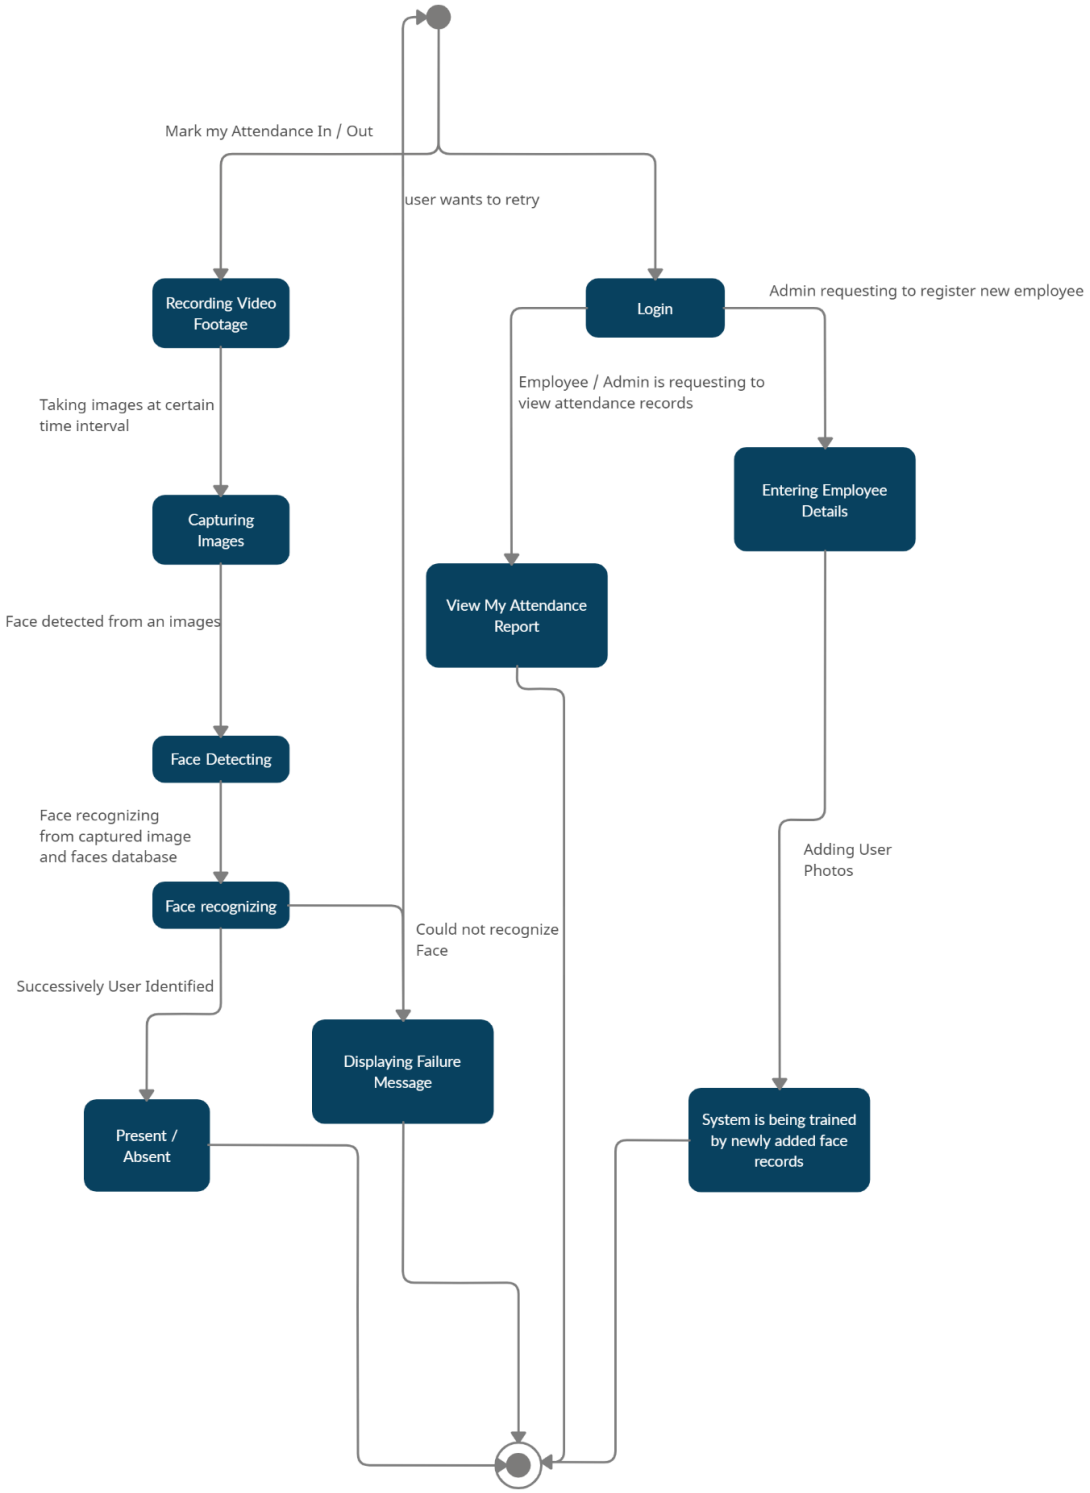
6.6 Class Diagram:

The **Class Diagram** represents the structure of the system in terms of classes and relationships.



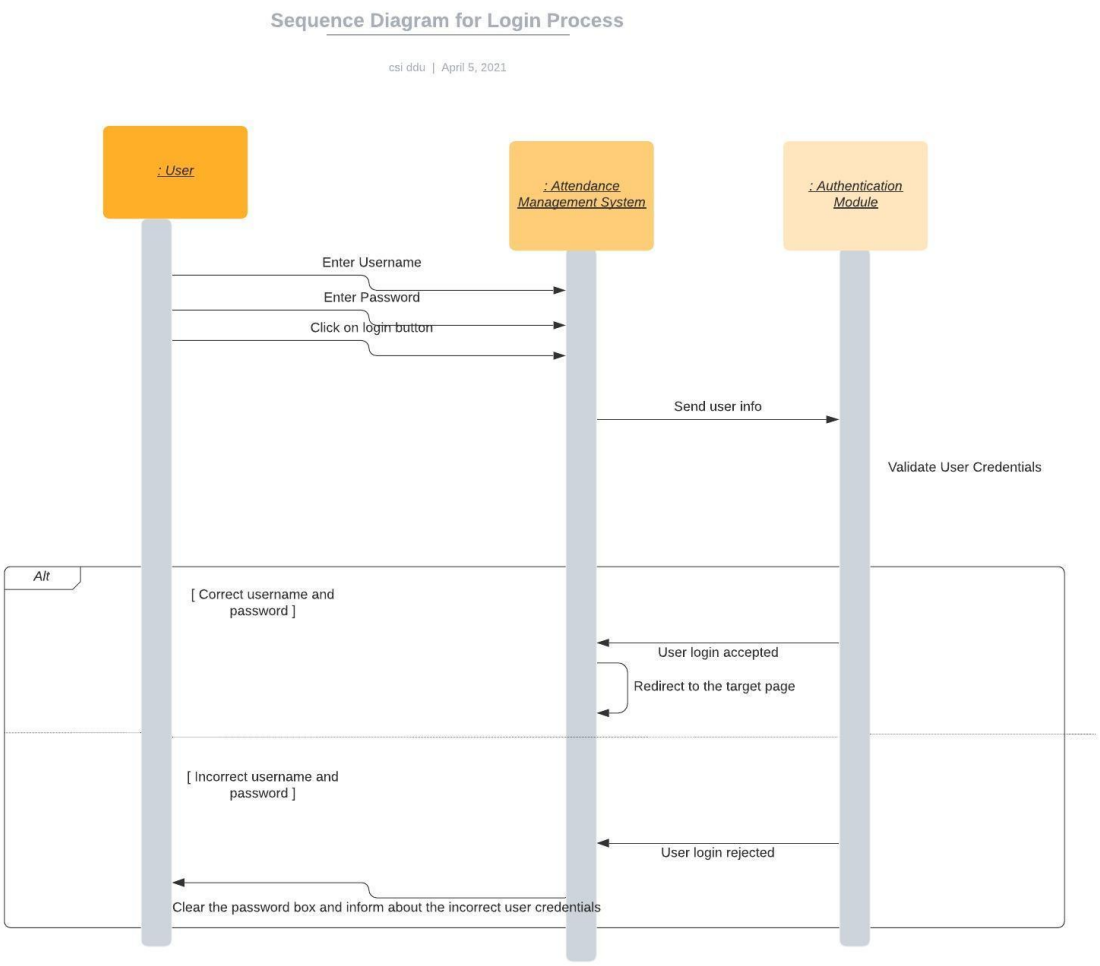
6.7 State Diagram:

The **State Diagram** shows different states of a user within the system.



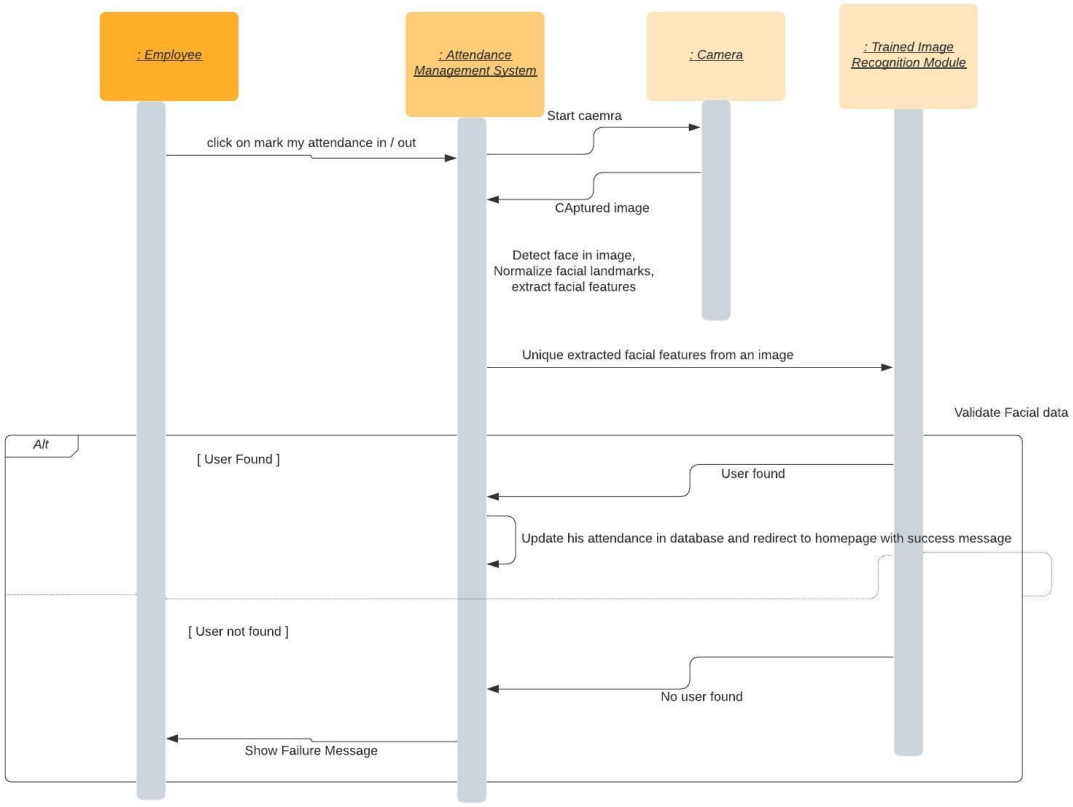
6.8 Sequence Diagram:

A **Sequence Diagram** shows how objects interact with each other in a time sequence.



Sequence Diagram for Login Process

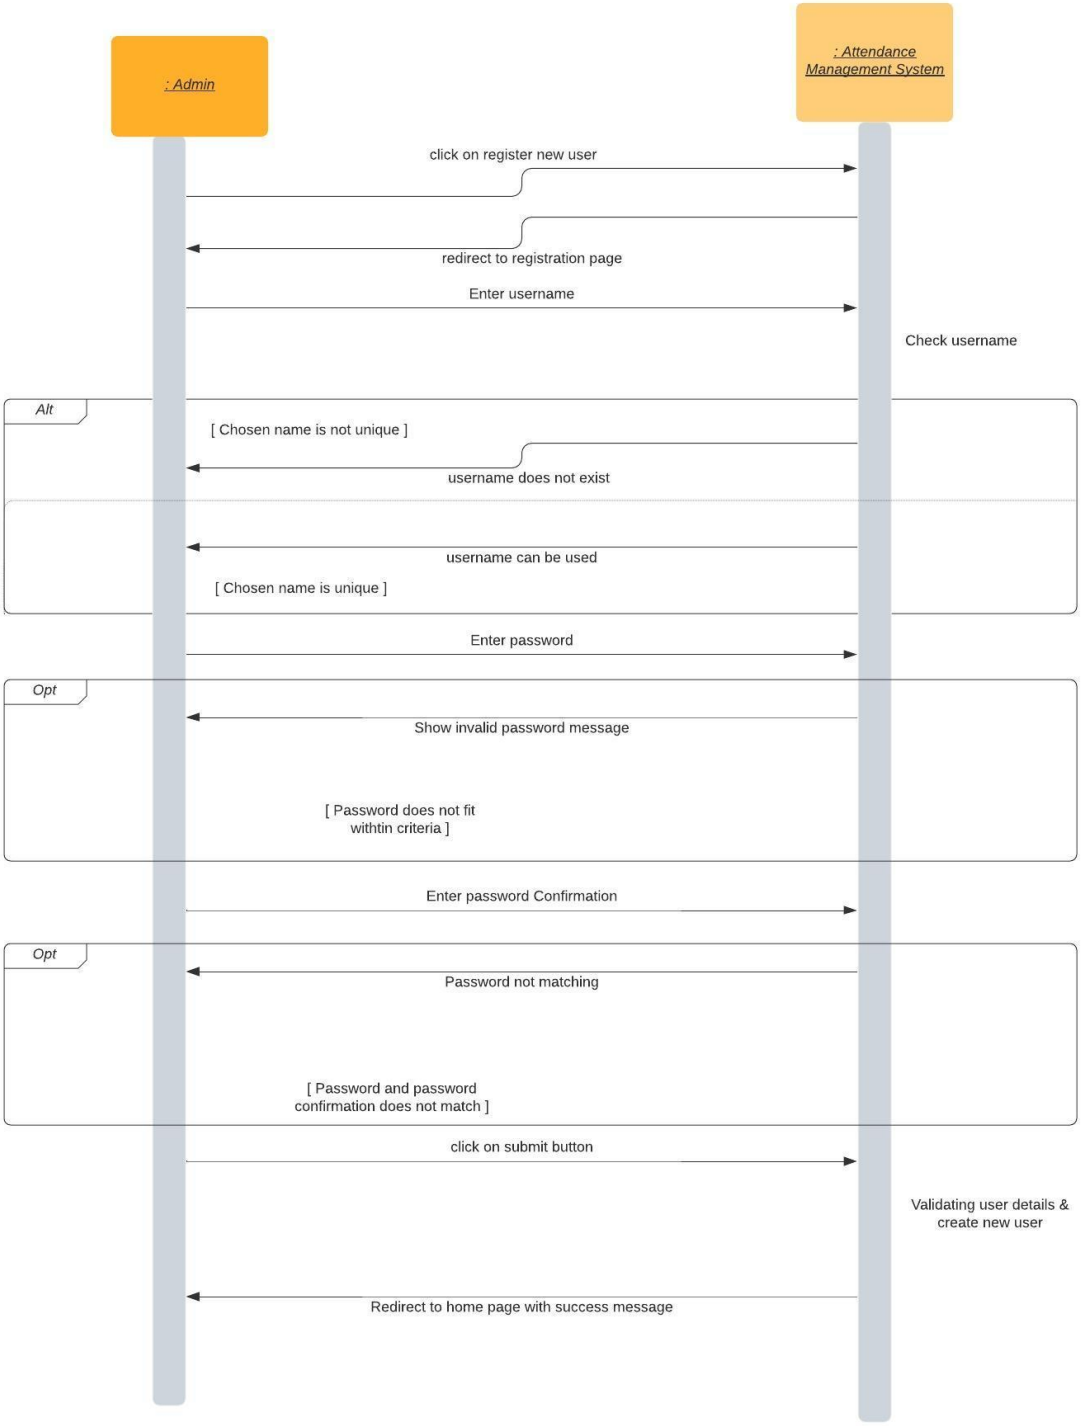
csi ddu | April 5, 2021



Sequence Diagram for register user Process

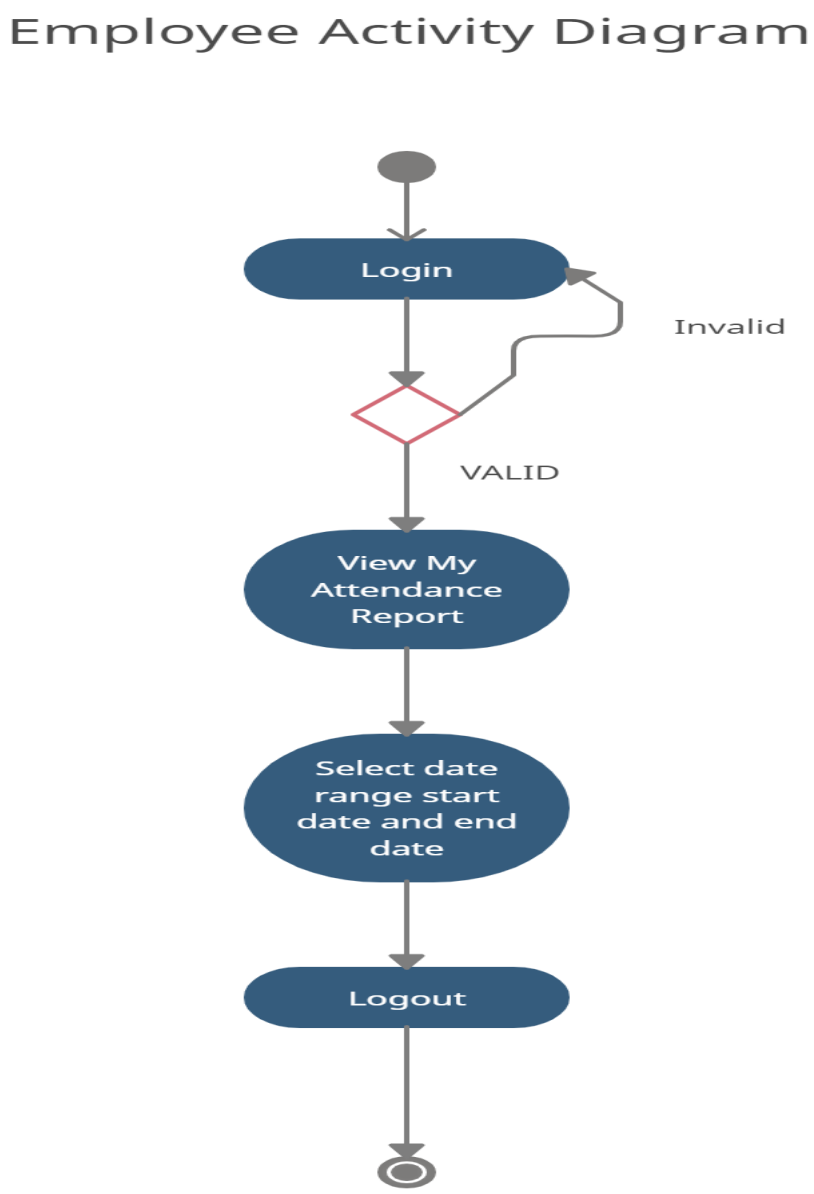
Text

csi ddu | April 5, 2021

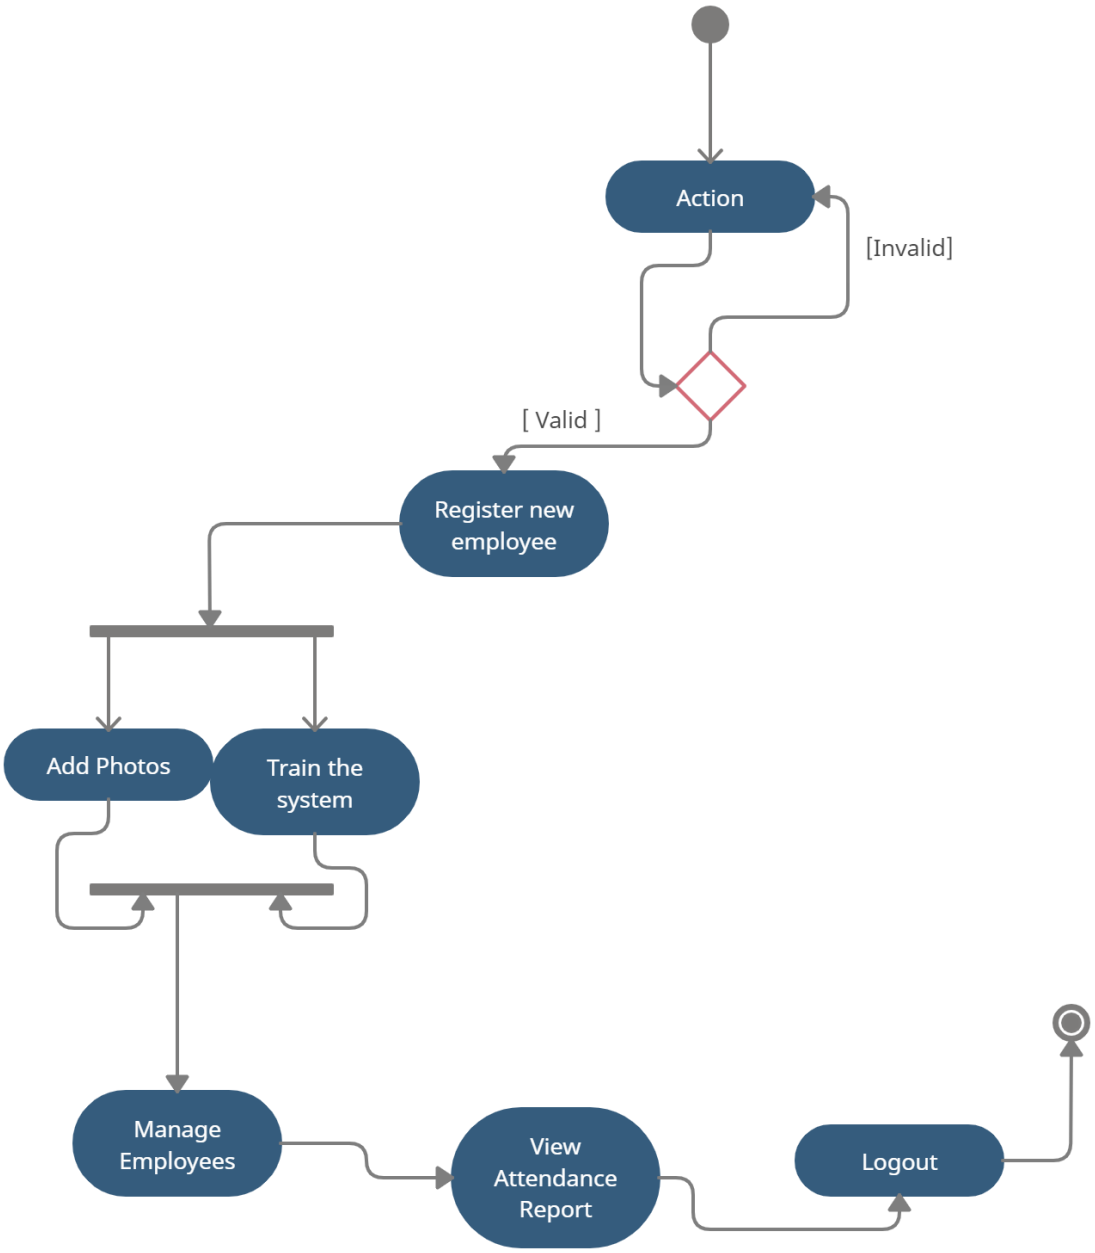


6.9 Activity Diagram:

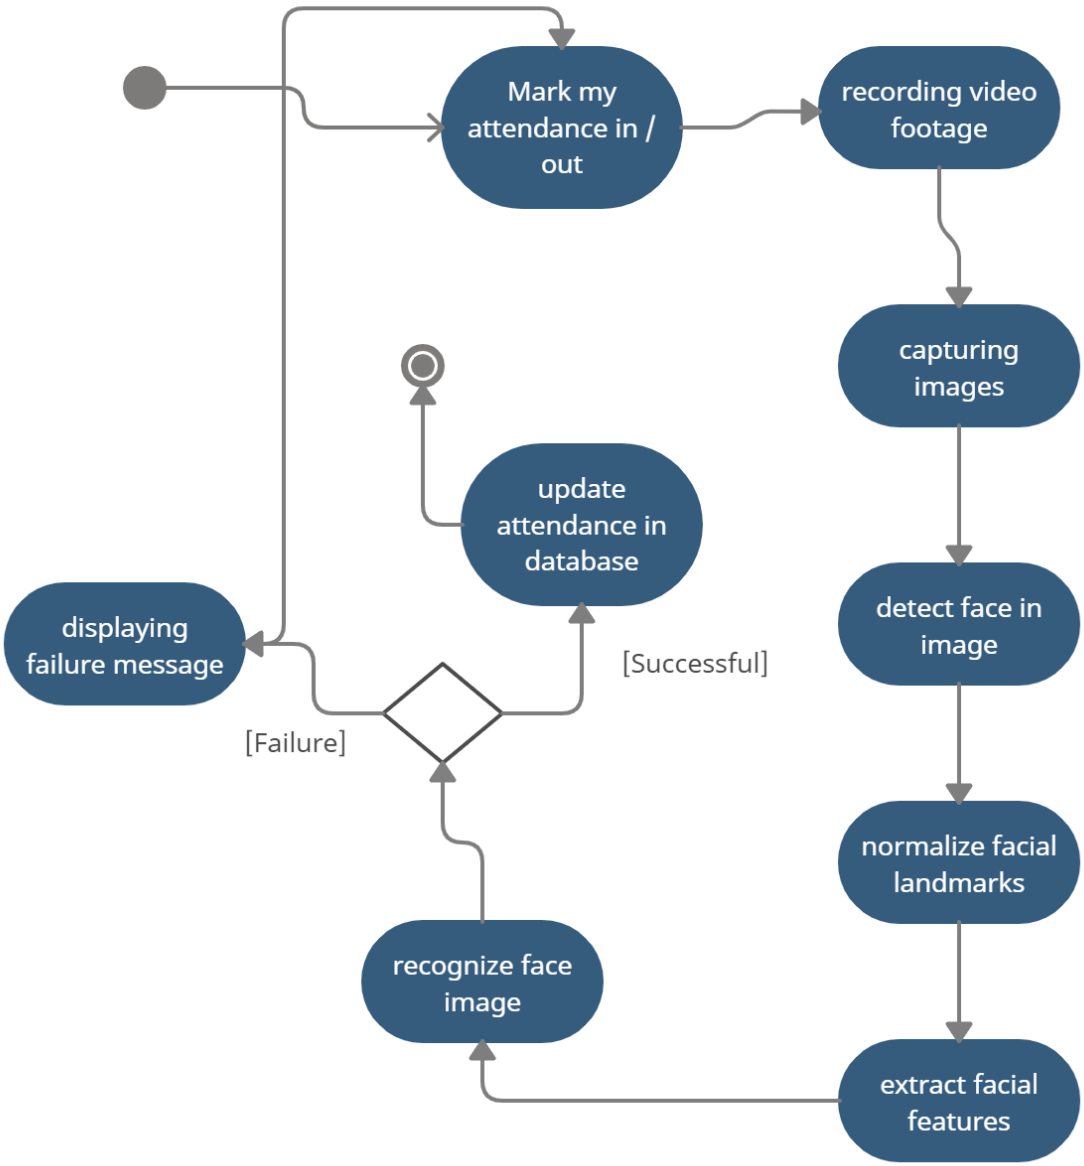
The **Activity Diagram** represents the workflow of the system.



Admin Activity Diagram



Attendance Tracking Activity Diagram

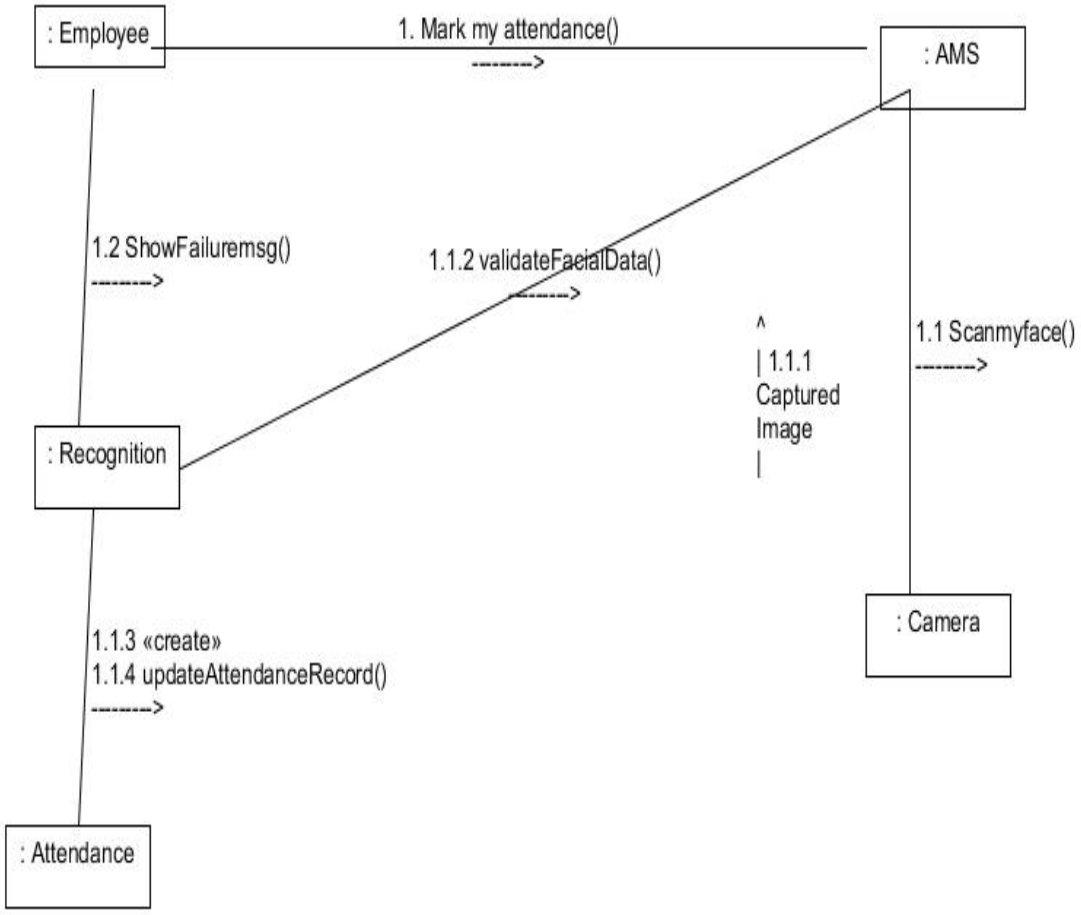


6.10 Collaboration Diagram:

A **Collaboration Diagram** shows how objects communicate with each other to perform system functions.

Objects involved:

- User Interface
- Face Recognition Module
- Database
- Admin Panel



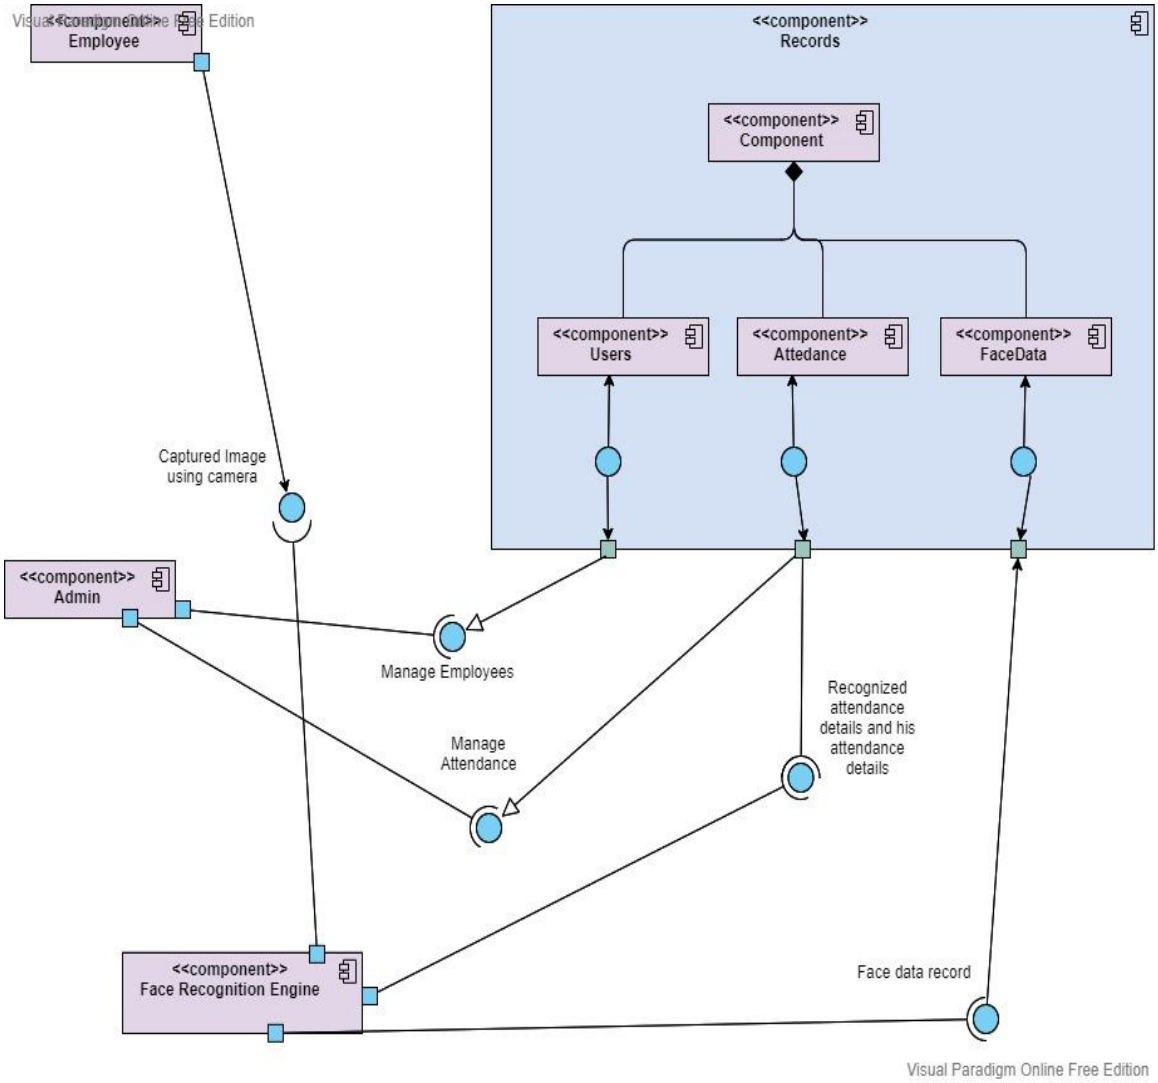
6.11 Component Diagram

The **Component Diagram** represents different software components used in the system.

Main components include:

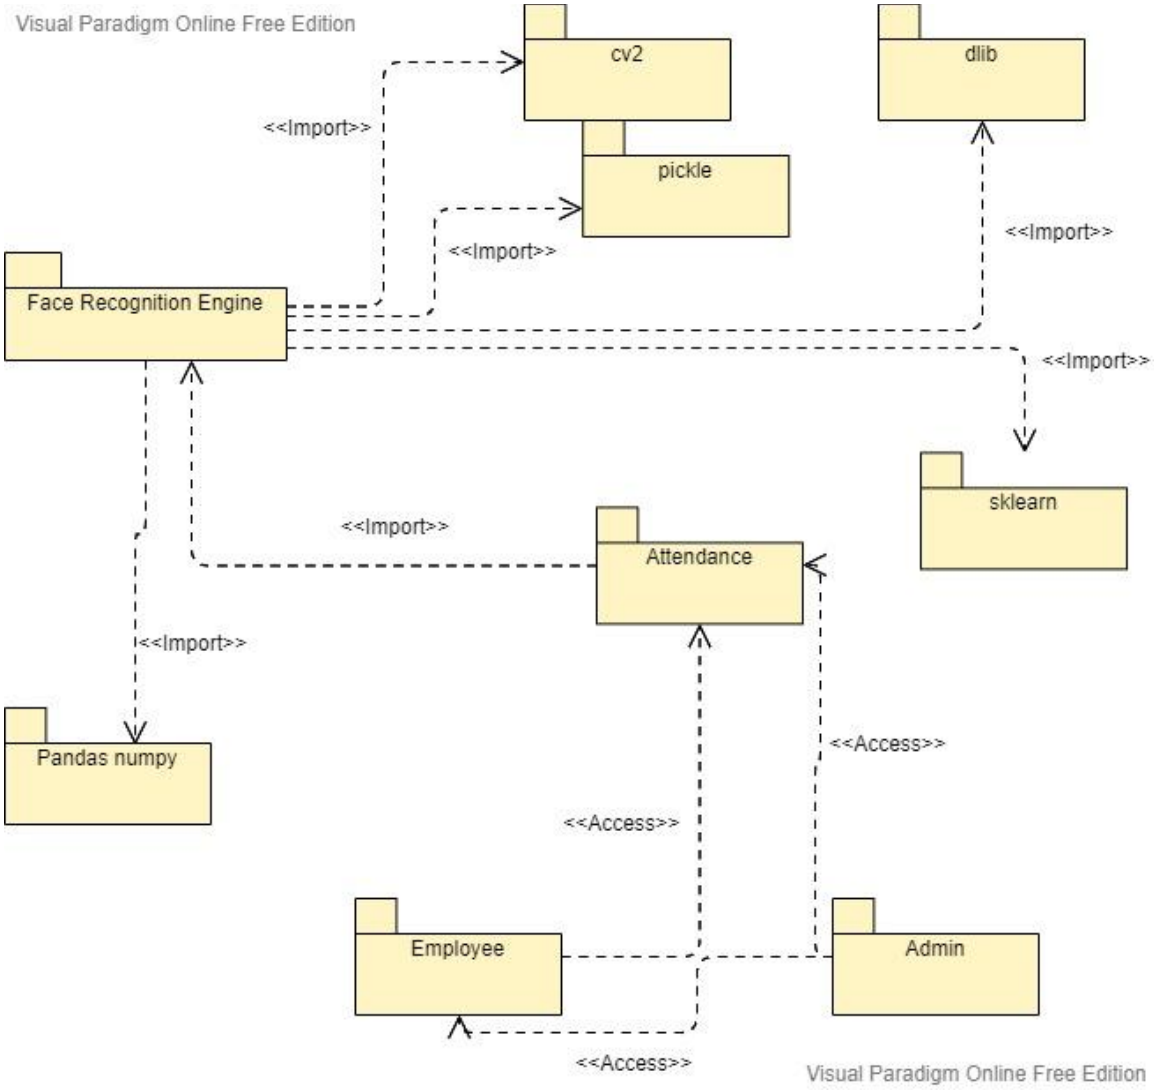
- Web Interface (HTML, CSS, JavaScript)
- Flask Application Server
- Face Recognition Module (OpenCV)
- Database System (MySQL)
- Admin Management Module

Each component interacts with others to perform system operations.



6.12 Package Diagram:

A **Package Diagram** organizes system components into logical groups.



7. METHODOLOGY / WORKING OF THE SYSTEM

The Smart Attendance System follows a **client–server request–response architecture**. The user interacts with the system through a web browser, while the backend server processes requests, performs face recognition, and stores data in the database.

The system operates through two main roles: **User Side** and **Admin Side**.

User Side Workflow:

1. The user opens the web application using a browser and selects either **Register** or **Mark Attendance**.
2. **Registration Process**
   - The user fills in personal details such as **name, email, and roll number**.
   - The server validates the entered information to ensure that the name format is correct and the email and roll number are unique.
   - After successful validation, the user is redirected to the **Capture Photo page**.
   - The browser requests permission to access the camera.
   - The user captures a photograph using the webcam.
   - The captured image is converted into **Base64 format** and sent to the server.
3. **Face Processing**
   - The server detects the face from the image using OpenCV.
   - A **face encoding** is generated based on facial features.
   - The system checks for duplicate faces to prevent multiple registrations by the same person.
   - If no duplicate is found, the user information and face encoding are stored in the **users table** in the database.
4. **Attendance Process**
   - The user opens the **Mark Attendance** page.
   - The user captures a photo through the webcam.
   - The browser sends the image to the server.
   - The server extracts the face encoding and compares it with all stored encodings in the database.
   - If a match is found and the attendance has not been marked for that day, a new record is inserted into the **attendance table**.
   - A success message is displayed to the user.

Admin Side Workflow

1. The administrator logs in using a **username and password**.
2. The server verifies the credentials stored in the **admin table**.
3. If authentication is successful, a **session is created** for the admin.
4. The admin can perform several actions such as:
    - Viewing the **dashboard statistics**.
    - Viewing a list of all registered users.
    - Checking today's attendance report.
    - Viewing monthly attendance reports.
5. The admin can also manage the system by clearing attendance records or deleting users from the database.

Technology Flow:

The system architecture consists of three main layers:

Presentation Layer

- HTML
- CSS
- JavaScript
- Bootstrap

This layer runs in the browser and handles user interaction.

Application Layer

- Flask (Python)
- FaceRecognitionUtils module
- Database configuration

This layer processes business logic, handles requests, performs face recognition, and communicates with the database.

Data Layer

- MySQL Database

This layer stores user information, face encodings, and attendance records for long-term data persistence.

8. MODULES OF THE SYSTEM

The Smart Attendance System is divided into several modules, each responsible for specific functionalities within the application.

8.1 Registration Module

The Registration Module is responsible for adding new users to the system.

In this module, the user enters personal details such as **name, email address, and roll number**. The system validates the entered information to ensure that the name format is correct and that the email and roll number are unique.

Once validation is successful, the user is redirected to the **capture photo page** where the system activates the webcam. The captured image is processed to detect the face and generate a **face encoding**.

Before storing the data, the system performs a **duplicate face check** by comparing the encoding with existing records. If the face is unique, the user details along with the face encoding are stored in the **users table**.

Flash messages are displayed to inform the user whether the registration was successful or if any errors occurred.

8.2 Face Detection & Recognition Module

This module handles the detection and recognition of faces within captured images. The functionality is implemented in the **utils/face_utils.py** file.

The module uses **OpenCV Haar Cascade Classifier** to detect faces in the captured image. The image is first converted to **grayscale format** to simplify processing.

After detecting the face region, the system performs the following steps:

- Resize the detected face image to **100 × 100 pixels**.
- Generate an **encoding vector** based on statistical features such as mean, standard deviation, median, minimum, and maximum pixel values.
- Normalize the encoding to ensure consistency.

The **compare_faces()** function compares the captured encoding with stored encodings using **cosine similarity distance**.

If the distance value is below the defined tolerance level, the system considers the faces to be a match.

This module is used during both **registration (duplicate face check)** and **attendance marking (identity verification)**.

8.3 Attendance Marking Module

The Attendance Marking Module records attendance for registered users.

The user accesses the **Mark Attendance page** and captures their facial image using the webcam. The browser sends the captured image to the server using the route **/mark_attendance_with_photo**.

The server processes the image by extracting the face encoding and retrieving all stored user encodings from the database. The system then compares the captured encoding with stored encodings to identify the user.

If a matching user is found and the user has not already marked attendance for the current day, the system inserts a new record into the **attendance table** with the following fields:

- user_id
- date
- time

If the user has already marked attendance or if the face is not recognized, the system returns an appropriate message to the user.

8.4 Reporting Module

The Reporting Module generates attendance reports for administrative monitoring and analysis.

Two main reports are provided:

Today's Report

This report displays the list of users who have marked attendance on the current day. The data is retrieved using a **JOIN operation** between the attendance table and the users table.

The report includes the following information:

- Name
- Roll Number
- Time of Attendance

Monthly Report

This report shows the total number of days each user was present in the current month. The data is calculated using **GROUP BY queries** and **COUNT functions** in SQL.

The reports are displayed in structured **HTML tables** for easy viewing.

8.5 Admin Dashboard:

The Admin Dashboard provides a summary view of system statistics.

After logging in, the admin can view important information such as:

- Total number of registered users
- Total attendance marked for the current day

The dashboard also provides navigation links to different modules such as:

- View Users
- Today's Attendance Report
- Monthly Attendance Report
- System Settings

The dashboard data is retrieved using SQL queries such as **SELECT COUNT(*)** from the users and attendance tables.

8.6 Admin Settings Module:

The Admin Settings Module allows the administrator to manage attendance data and user records.

Through this module, the admin can perform the following operations:

- Clear attendance records for a specific date
- Clear all attendance records
- Delete a specific user
- Delete all users from the system

The frontend sends **POST requests in JSON format** containing parameters such as type, date value, or user ID. The server verifies the admin session before executing the request.

After processing the request, the server returns a **JSON response** indicating whether the operation was successful.

This module ensures that the system remains organized and allows administrators to maintain accurate attendance records.

9. IMPLEMENTATION

Implementation is the phase where the system design is converted into a working application using programming languages and development tools.

The Smart Attendance System is implemented using **Python, Flask, OpenCV, and MySQL**.

9.1 Programming Code:

The project follows a structured folder organization to maintain clean and manageable code.

Project Structure

```
Smart_Attendance_System/
│
├── app.py
├── setup_database.py
├── init.sql
├── requirements.txt
│
├── config/

```

1. requirements.txt

This file contains all required Python libraries.

```
Flask
opencv-python
numpy
Pillow
mysql-connector-python
python-dotenv
```

Install using:

```
pip install -r requirements.txt
```

---

2. Database Configuration

config/database.py

This module handles the MySQL database connection.

```
import mysql.connector
import os

class DatabaseConfig:

    def __init__(self):
        self.host = os.getenv("DB_HOST", "localhost")
        self.database = os.getenv("DB_NAME", "attendance_system")
        self.user = os.getenv("DB_USER", "root")
        self.password = os.getenv("DB_PASSWORD", "")
        self.port = int(os.getenv("DB_PORT", 3306))

    def get_connection(self):
        connection = mysql.connector.connect(
            host=self.host,
            database=self.database,
            user=self.user,
            password=self.password,
            port=self.port
        )
        return connection
```

Description

This module:

- Stores database credentials
- Establishes connection with MySQL

- Returns connection object for queries

---

3. Face Detection and Recognition

utils/face_utils.py

This module processes facial images.

```
import cv2
import numpy as np

class FaceRecognitionUtils:

    def __init__(self):
        self.face_cascade = cv2.CascadeClassifier(
            cv2.data.haarcascades +
'haarcascade_frontalface_default.xml'
        )

    def detect_face(self, image):

        gray = cv2.cvtColor(image, cv2.COLOR_BGR2GRAY)

        faces = self.face_cascade.detectMultiScale(
            gray,
            scaleFactor=1.3,
            minNeighbors=5
        )

        if len(faces) == 0:
            return None

        x, y, w, h = faces[0]

        face = gray[y:y+h, x:x+w]

        face = cv2.resize(face, (100, 100))

        return face

    def generate_encoding(self, face):

        hist = cv2.calcHist([face], [0], None, [256], [0, 256])
        hist = cv2.normalize(hist, hist).flatten()

        stats = np.array([
            np.mean(face),
            np.std(face),
            np.median(face),
            np.min(face),
            np.max(face)
```

```
        ])

        encoding = np.concatenate((hist, stats))

```

Description

This module performs:

Face Detection

- Uses OpenCV Haar Cascade
- Detects face in captured image

Face Encoding

Extracts facial features using:

- Histogram
- Mean
- Standard deviation
- Median
- Min/Max

Face Comparison

Uses **cosine similarity** to compare face encodings.

4. Database Setup

setup_database.py

This script creates the database and tables.

```
import mysql.connector

connection = mysql.connector.connect(
    host="localhost",
    user="root",
    password=""
)

cursor = connection.cursor()

cursor.execute("CREATE DATABASE IF NOT EXISTS attendance_system")

cursor.execute("USE attendance_system")

cursor.execute("""
CREATE TABLE IF NOT EXISTS users(
    id INT AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(60),
    email VARCHAR(100) UNIQUE,
    roll_number VARCHAR(20) UNIQUE,
    face_encoding LONGTEXT
)
""")

cursor.execute("""
CREATE TABLE IF NOT EXISTS attendance(
    id INT AUTO_INCREMENT PRIMARY KEY,
    user_id INT,
    date DATE,
    time TIME,
    FOREIGN KEY(user_id) REFERENCES users(id)
)
""")

cursor.execute("""
CREATE TABLE IF NOT EXISTS admin(
    id INT AUTO_INCREMENT PRIMARY KEY,
    username VARCHAR(50),
    password VARCHAR(100)
)
""")

cursor.execute("""
INSERT INTO admin(username,password)
VALUES('admin','admin123')
```

```
""")

connection.commit()

print("Database setup completed")
```

---

Explanation of System Workflow

The Smart Attendance System operates in the following sequence:

1. User registers with personal details and facial image.
2. The system processes the image and generates a face encoding.
3. The encoding is stored in the database.
4. When marking attendance, the user captures their face.
5. The system compares the captured face encoding with stored encodings.
6. If a match is found, attendance is recorded with date and time.
7. The administrator can view attendance reports through the dashboard.

9.2 Testing Approach:

Testing was conducted to ensure that the Smart Attendance System works correctly under both normal and error conditions. The system was tested using **positive test cases** and **negative test cases**.

Positive Testing

Positive testing verifies that the system works correctly when valid inputs are provided.

Examples include:

- Valid user registration
- First-time attendance marking
- Admin login with correct credentials
- Viewing attendance reports
- Clearing attendance or deleting users

Negative Testing

Negative testing ensures the system handles incorrect or invalid inputs properly.

Examples include:

- Duplicate email or roll number during registration
- Attempting attendance with an unregistered face
- Attempting to mark attendance multiple times in the same day
- Admin login with incorrect credentials
- Accessing admin pages without authentication

The results of these tests are recorded in the following test case table.

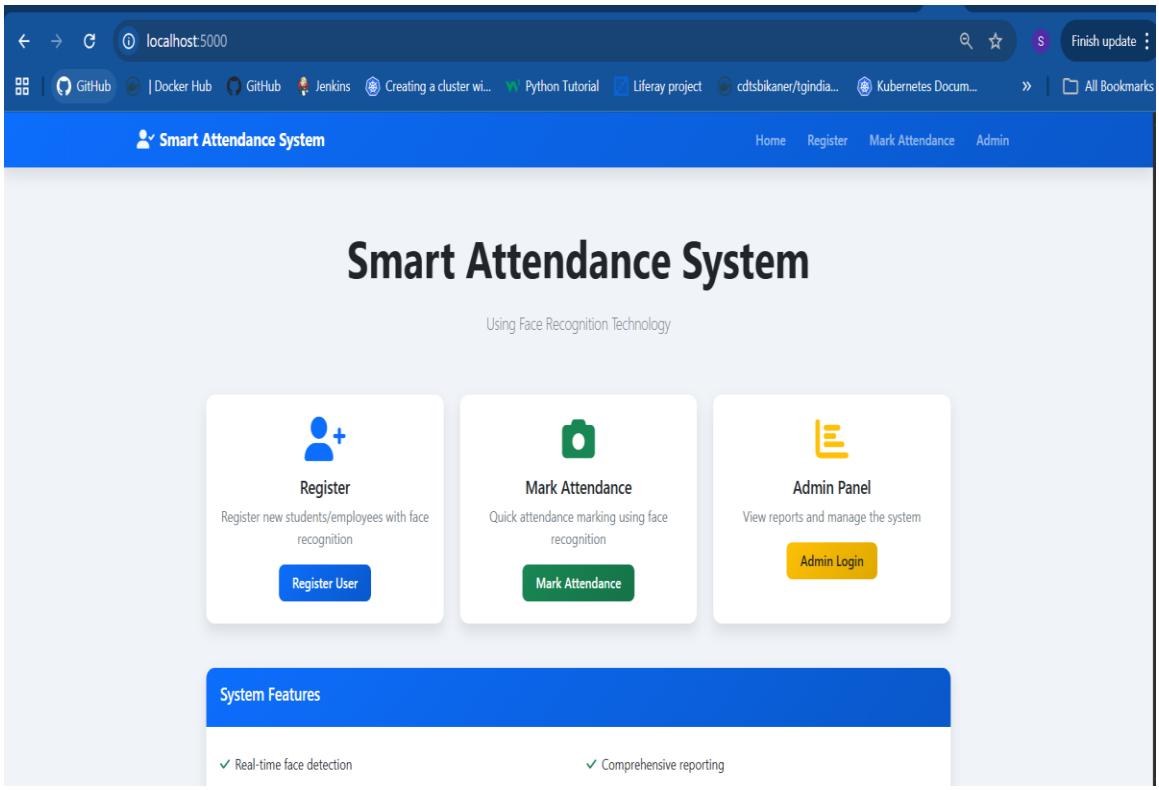
Table 9.1 – Test Cases and Results

TC	Description	Expected Result	Status (Pass/Fail)
1	New user registration (valid data)	User created and visible in All Users list	Pass
2	Duplicate roll number	Error message "Roll number already registered"	Pass
3	Duplicate email	Error message "Email already registered"	Pass
4	Mark attendance (first time today)	Attendance recorded in Today's Report	Pass
5	Mark attendance (same day again)	Message "Attendance already marked today"	Pass
6	Unregistered face	Message "Face not recognized"	Pass
7	Admin login (correct credentials)	Admin dashboard displayed	Pass
8	Admin login (wrong credentials)	Message "Invalid credentials"	Pass
9	View reports	Correct attendance data displayed	Pass
10	Clear attendance / Delete user	Success confirmation message	Pass
11	Access admin page without login	Redirect to admin login page	Pass

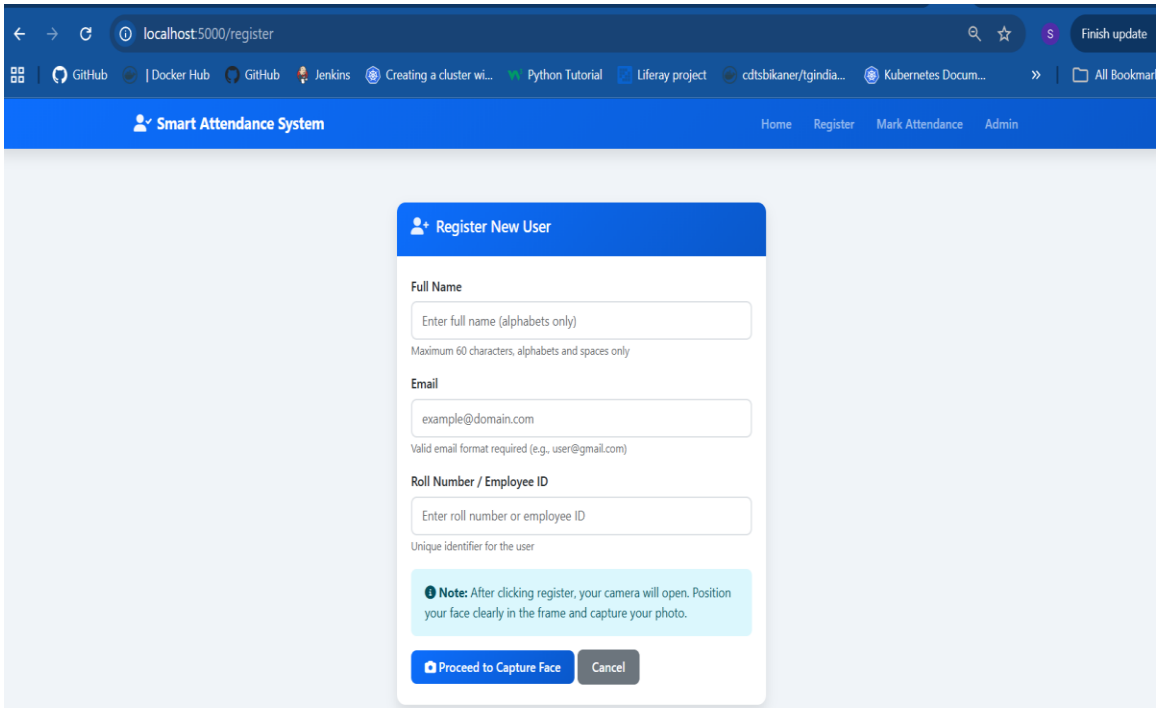
9.3 Results and Screenshots:

The following screenshots demonstrate the successful execution of different modules of the Smart Attendance System. These screenshots should be captured during system execution and inserted at the appropriate places in the report.

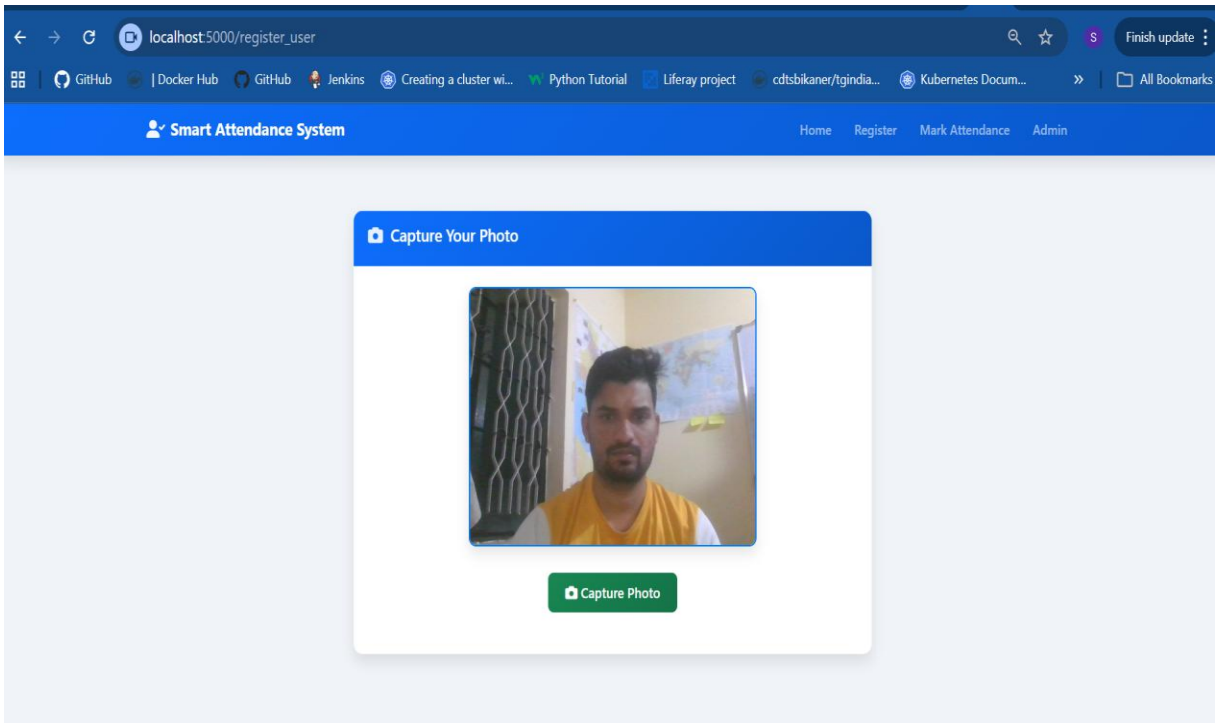
9.3.1 Home Page



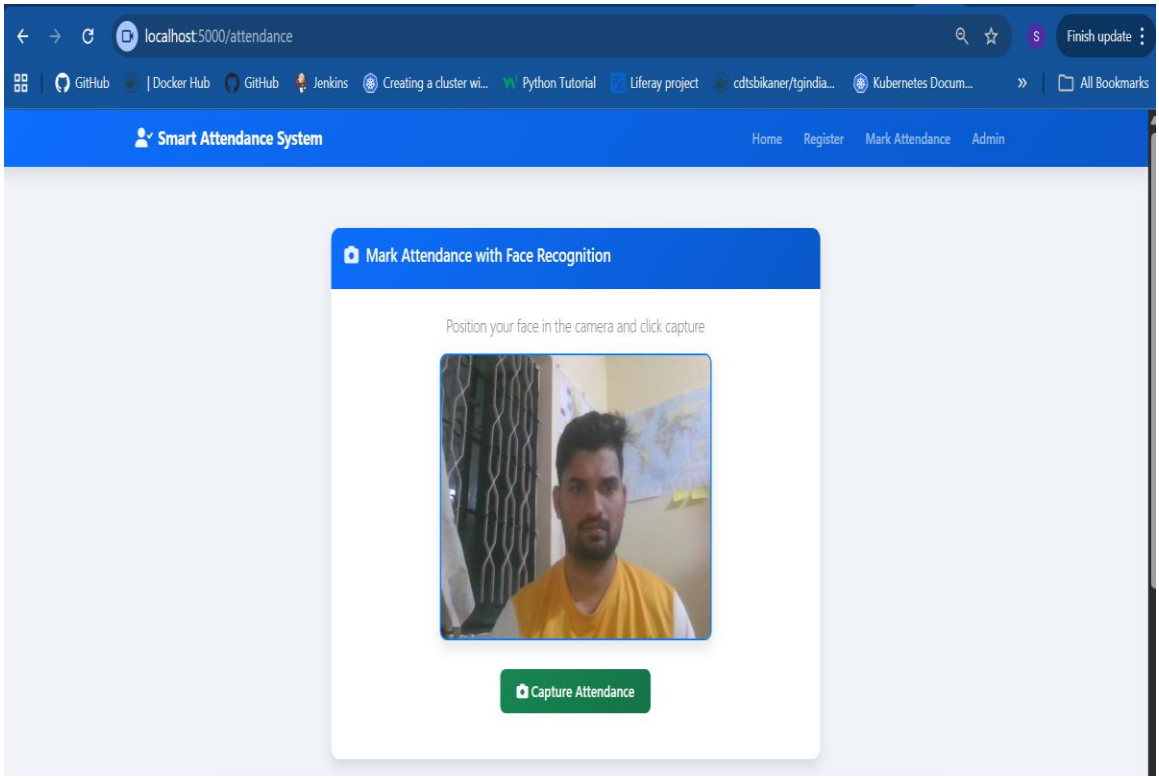
9.3.2 Register Page



9.3.3 Capture Photo (Registration)

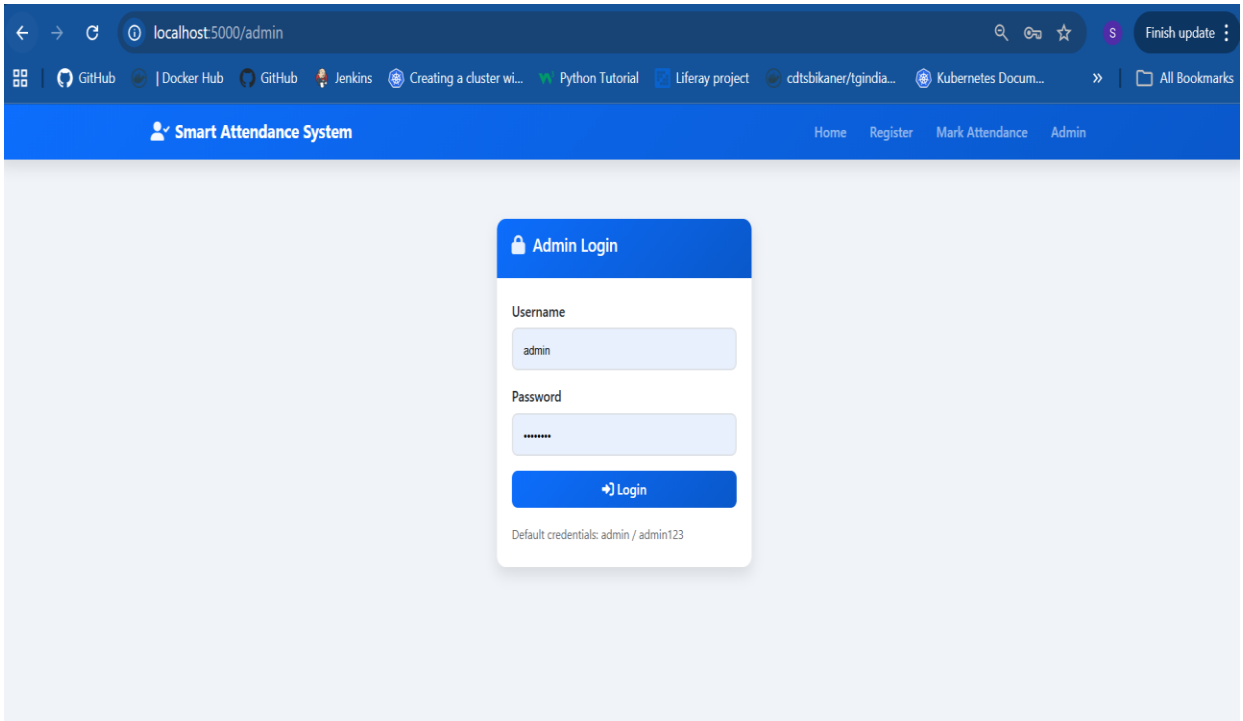


9.3.4 Mark Attendance Page

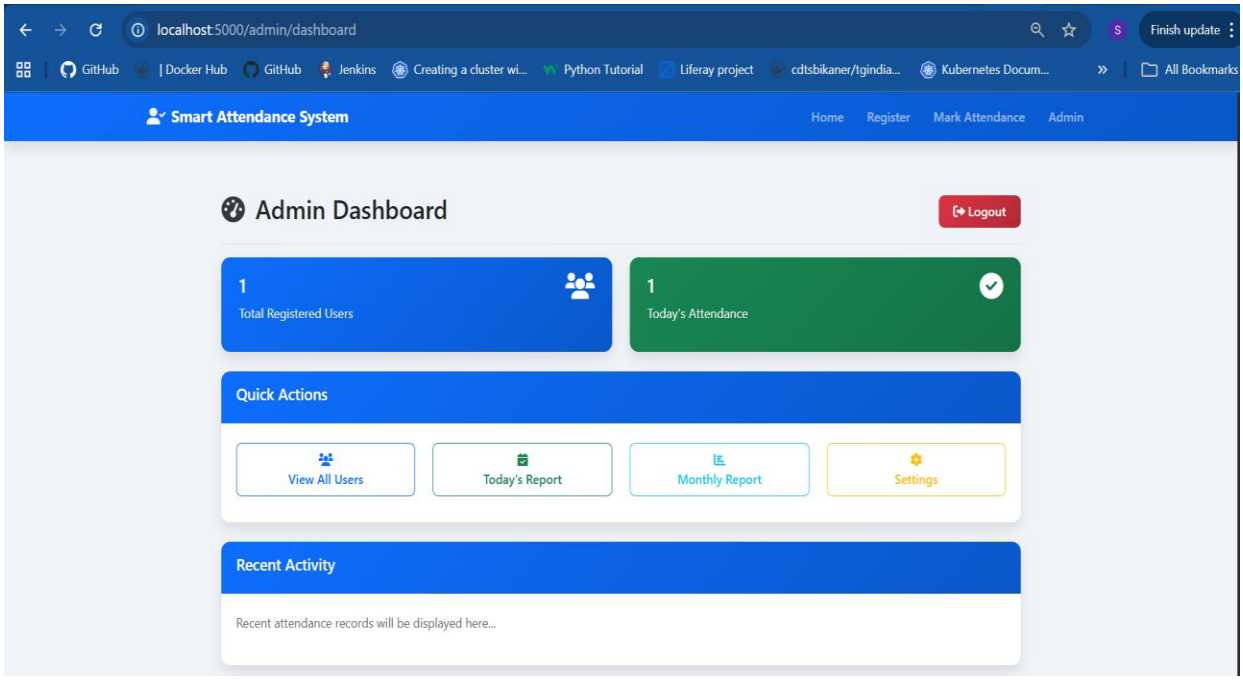


.

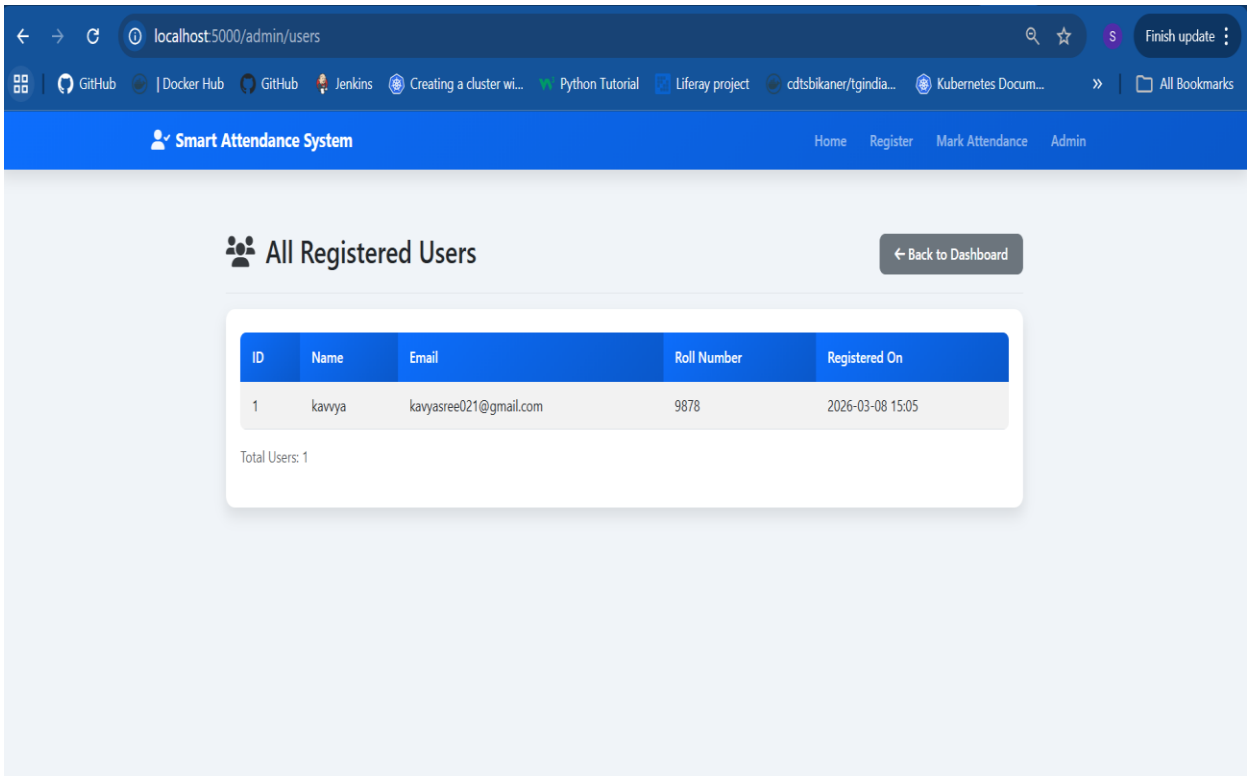
9.3.5 Admin Login Page



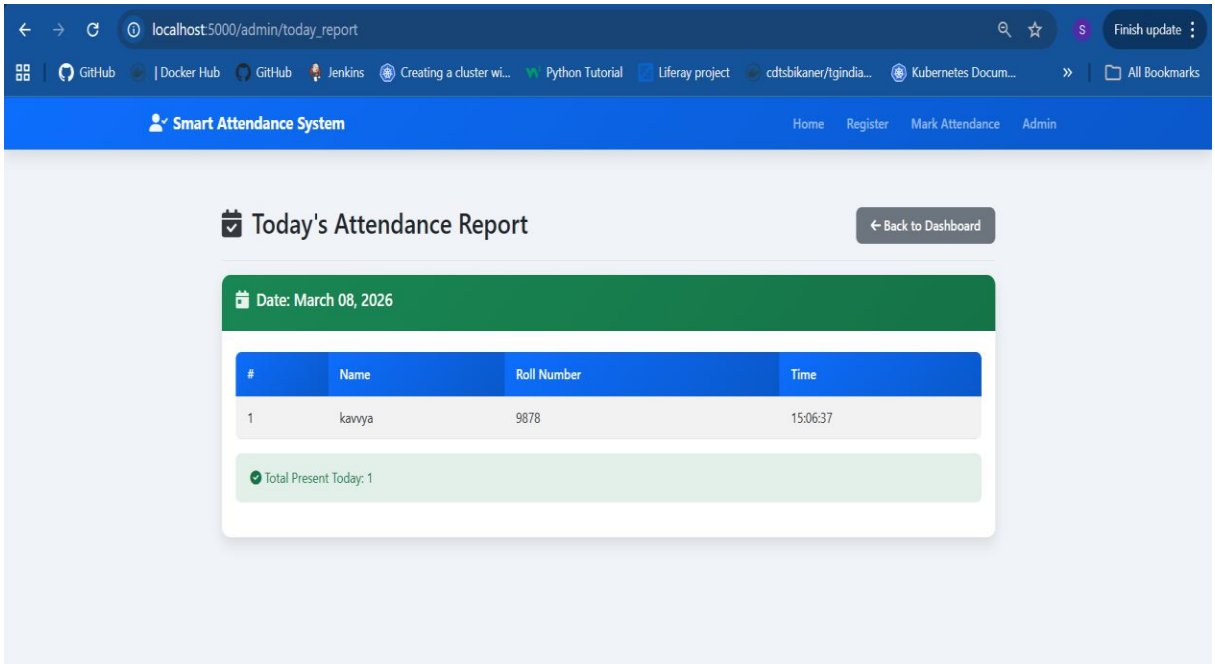
9.3.6 Admin Dashboard



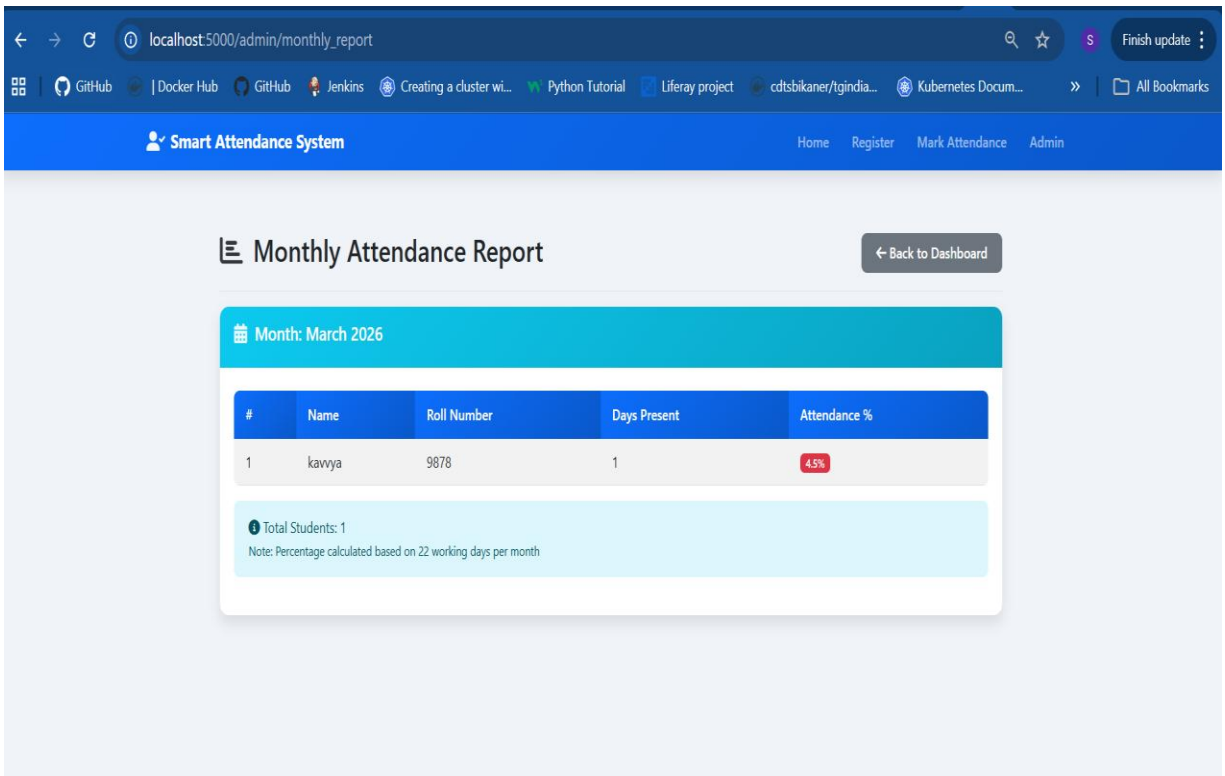
9.3.7 All Registered Users



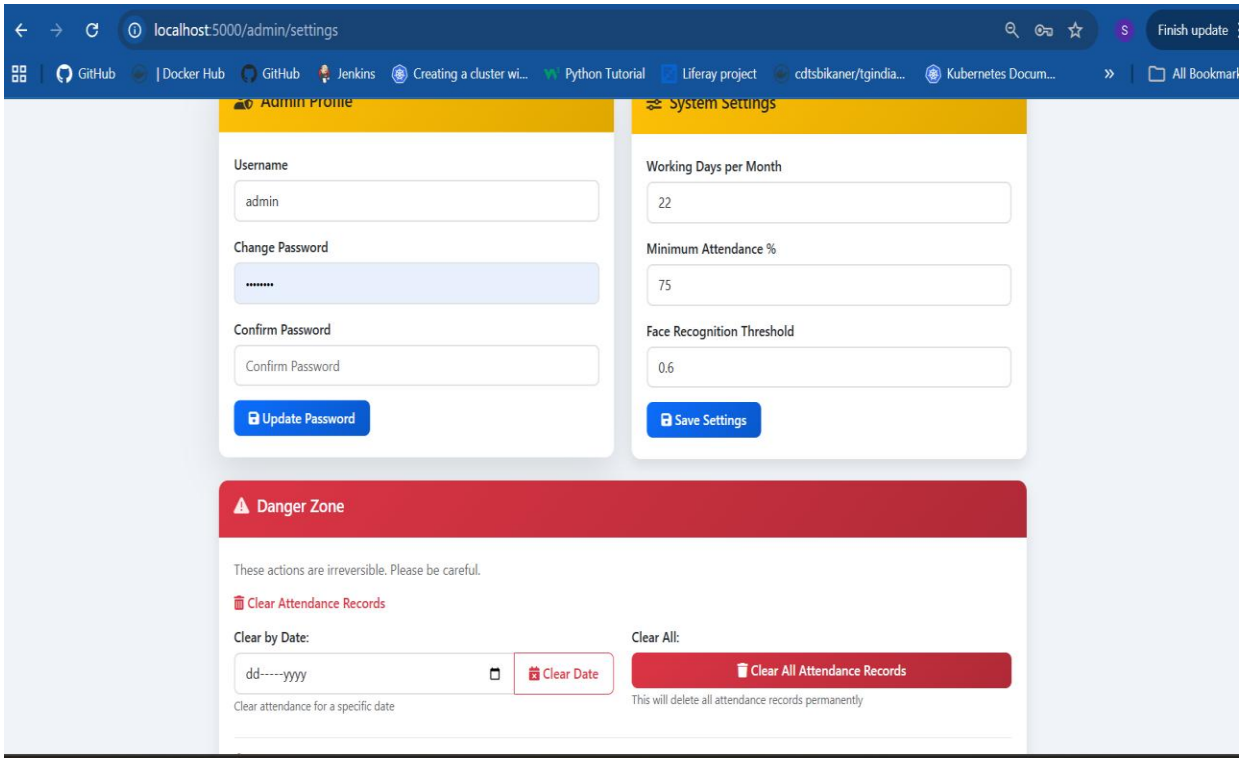
9.3.8 Today's Attendance Report



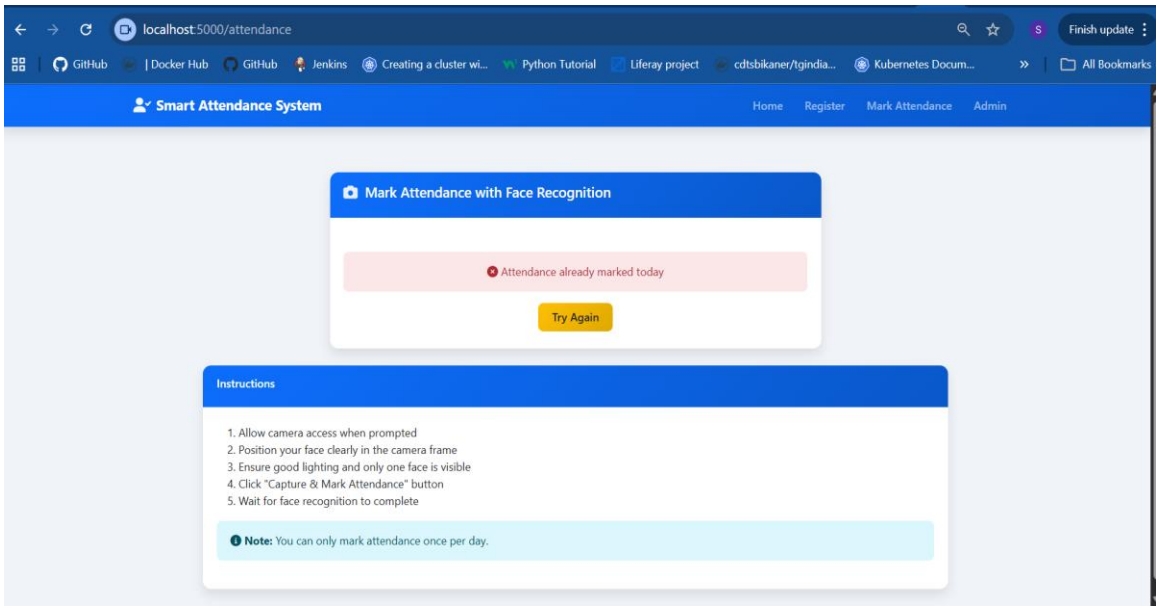
9.3.9 Monthly Attendance Report



9.3.10 Admin Settings (Danger Zone)



9.3.11 Success Message



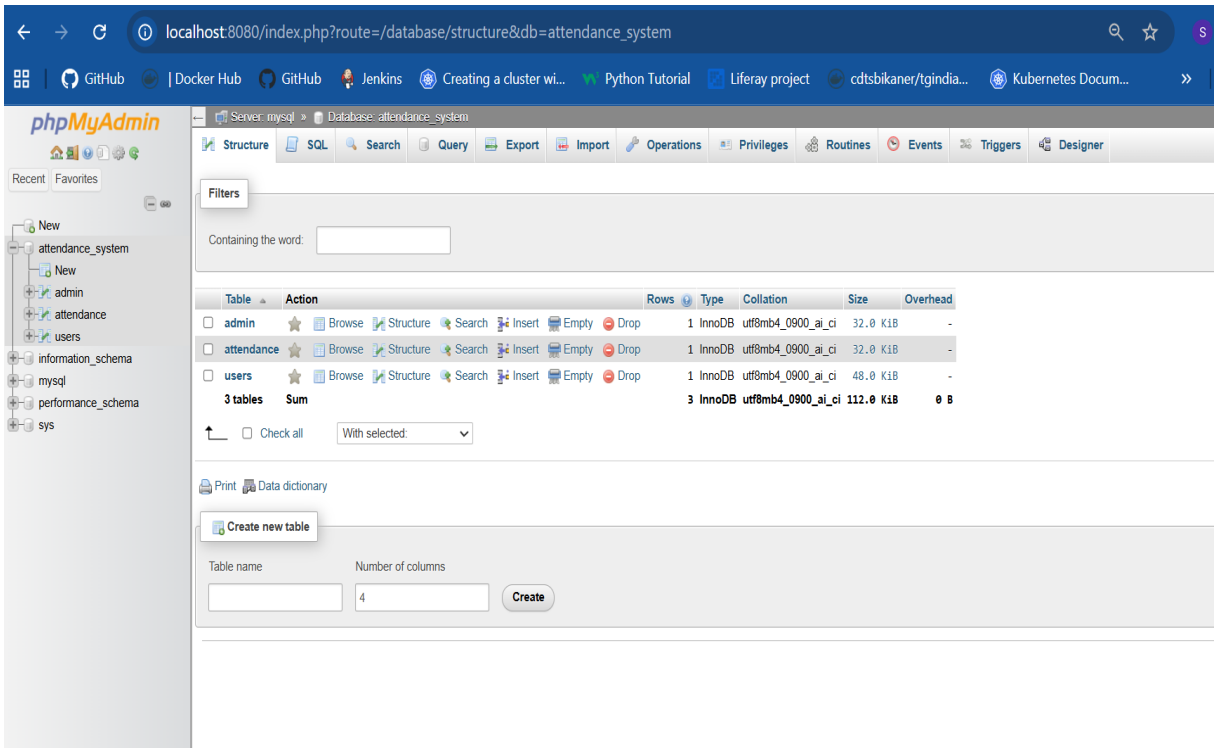
9.3.12 Database Schema

Database_Schema_phpMyAdmin_Users_Attendance_Admin.png

This screenshot shows the database tables created in **phpMyAdmin** including:

- `users`
- `attendance`
- `admin`

The schema includes column names, data types, primary keys, and foreign keys.



10. CONCLUSION (Limitations, Future Scope)

10.1 Conclusion

The **Smart Attendance System** developed in this project provides an efficient and automated solution for managing attendance using face recognition technology. Traditional attendance methods such as manual registers or card-based systems often consume time and are prone to errors, manipulation, and proxy attendance. To overcome these issues, the proposed system integrates modern web technologies and image processing techniques to create a reliable and user-friendly attendance management system.

The application allows users to **register their personal details along with their facial image**. Once the registration process is completed, the system stores the facial encoding generated from the captured image in a database. Whenever the user wants to mark attendance, the system captures the user's face through the browser camera and compares the extracted facial features with the stored encodings in the database. If a match is found, the system records the attendance along with the date and time.

The system also provides an **administrator interface** that enables efficient management of users and attendance data. The administrator can log into the system using secure credentials and access various features such as viewing the dashboard, monitoring total registered users, checking daily attendance records, generating monthly reports, and managing system data by clearing attendance records or deleting user accounts when necessary.

The project has been implemented using **Flask as the web framework, OpenCV for face detection, MySQL for database management, and Bootstrap for the user interface**. These technologies work together to create a lightweight and efficient web-based application that can be easily deployed on a local server or within an institutional network.

During the development of this system, several important objectives were successfully achieved:

- Automation of the attendance process using facial recognition.
- Elimination of proxy attendance through biometric verification.
- Simple and user-friendly web interface for both users and administrators.
- Efficient storage and retrieval of attendance records using a relational database.
- Instant generation of attendance reports for administrative purposes.

The system also demonstrates how **computer vision and web development technologies can be integrated** to build practical real-world applications. Overall, the Smart Attendance System improves efficiency, reduces manual effort, and ensures accuracy in attendance management.

The project serves as a strong foundation for further improvements and enhancements that can make the system more scalable, secure, and suitable for large-scale institutional environments.

10.2 Limitations:

Although the Smart Attendance System performs its intended functions successfully, it still has certain limitations that can be improved in future versions.

1. Lighting Dependency

The accuracy of face recognition depends on proper lighting conditions. If the environment has **low lighting or excessive brightness**, the system may fail to detect the face correctly.

2. Frontal Face Requirement

The current implementation works best when the user's face is **directly facing the camera**. If the face is partially turned, covered, or captured at a large angle, recognition accuracy may decrease.

3. Limited Security for Admin Credentials

In the current implementation, the administrator password is stored in **plain text format** in the database. This method is not fully secure for production environments.

4. Single Administrator Account

The system currently supports only **one administrator account**, which means multiple administrators cannot manage the system simultaneously.

5. No Report Export Feature

The system allows viewing reports in the browser but does not currently support **exporting attendance reports to Excel or PDF files**.

6. Single Location System

The system is designed for **a single organization or classroom environment**. It does not currently support multiple branches, departments, or locations.

7. Basic Face Recognition Algorithm

The project uses a **basic histogram-based encoding method** for face comparison. While it works for demonstration purposes, more advanced models can provide better accuracy.

Despite these limitations, the system successfully demonstrates the concept of **automated attendance using face recognition** and can be further improved with additional features.

10.3 Future Scope:-

The Smart Attendance System can be enhanced in many ways to improve its performance, usability, and scalability. Some possible future improvements are described below.

1. Mobile Application Development

A dedicated **mobile application for Android and iOS** can be developed to allow users to register and mark attendance directly from their smartphones. Mobile apps provide better camera control and improved user experience.

2. Email and SMS Notifications

The system can be integrated with **email or SMS services** to send automatic notifications when attendance is marked or when reports are generated. This feature can help administrators monitor attendance activities more efficiently.

3. Advanced Deep Learning Face Recognition

The current recognition method can be replaced with advanced **deep learning models such as FaceNet, dlib, or deep CNN-based algorithms**. These models provide higher accuracy and better performance under different lighting and pose conditions.

4. Multi-Location Support

Future versions can support **multiple branches, departments, or classrooms**. Each branch can have separate attendance records and administrators.

5. Export Reports to Excel and PDF

The system can be enhanced to allow administrators to **download attendance reports in Excel or PDF format** for official documentation and analysis.

6. Secure Password Storage

Admin passwords should be stored using **secure hashing algorithms such as bcrypt or SHA-256** to improve system security.

7. Cloud Deployment

The system can be deployed on **cloud platforms such as AWS, Google Cloud, or Azure**, allowing access from multiple locations and improving scalability.

8. Real-Time Face Recognition

Future versions could implement **real-time face recognition**, where attendance is automatically recorded when the user enters the classroom without requiring manual capture.

9. Audit Log System

An **audit log feature** can be added to record all administrative actions such as user deletion or attendance clearing. This will improve accountability and security.

By implementing these improvements, the Smart Attendance System can evolve into a **fully scalable and enterprise-level attendance management solution**.
